ABSTRACT

The first *Ateuchus* Weber (Scarabaeinae) species, *A. tuza* sp. nov., from a rodent burrow from North America is described. Diagnostic characters are presented; photographs of an adult male and illustrations of male genitalia are included. A key for all known Mexican *Ateuchus* Weber species is provided. *Ateuchus hornai* (Balthasar) is revalidated. New distribution records from Mexico and Central America are reported.

Introduction

This work is a continuation of the study of the genus *Ateuchus* Weber for North America, first started in 1981 (Kohlmann, 1981, 1984; Kohlmann and Halffter, 1988), and thereafter extended to Mesoamerica (Kohlmann, 2000) and Costa Rica (Kohlmann, 1996–1997; Kohlmann and Solís, 2009, 2012). It describes the first known *Ateuchus* species from the burrow of a rodent collected in North America. *Ateuchus hornai* (Balthasar) is revalidated. This description and the present revalidation increase the number of previously known species from Mexico to fourteen. As a comparison, twelve species are known from Costa Rica (Kohlmann and Solís, 2012). This study also presents a key for the Mexican *Ateuchus* species. It also reports new *Ateuchus* records from Mexico and Central America.

Materials and methods

Most specimens studied came from the Entomology Section of the Zoological Collection of the *Universidade Federal de Mato*

Grosso, Cuiabá, Brazil (CEMT) and the Entomological Collection at the Institute of Ecology (IEXA), Xalapa, Mexico. Other collections are cited only once and so no acronyms are used for them.

The specimens were studied using a Zeiss Stemi 2000-C stereozoom binocular microscope. Measurements were made to the nearest 0.1 mm using an ocular micrometer. Genital dissections and preparations were done following the techniques described by Zunino (1978). Genital structures were stored in microvials with glycerin. The structures of the internal sac were drawn using the freehand technique. Photographs were taken with a Zeiss AxioCam ICc1 camera. Photographs were processed using the Zeiss Axio-Vision 4 image processor. Morphological nomenclature follows Kohlmann (1984, 2000) and Génier (2015).

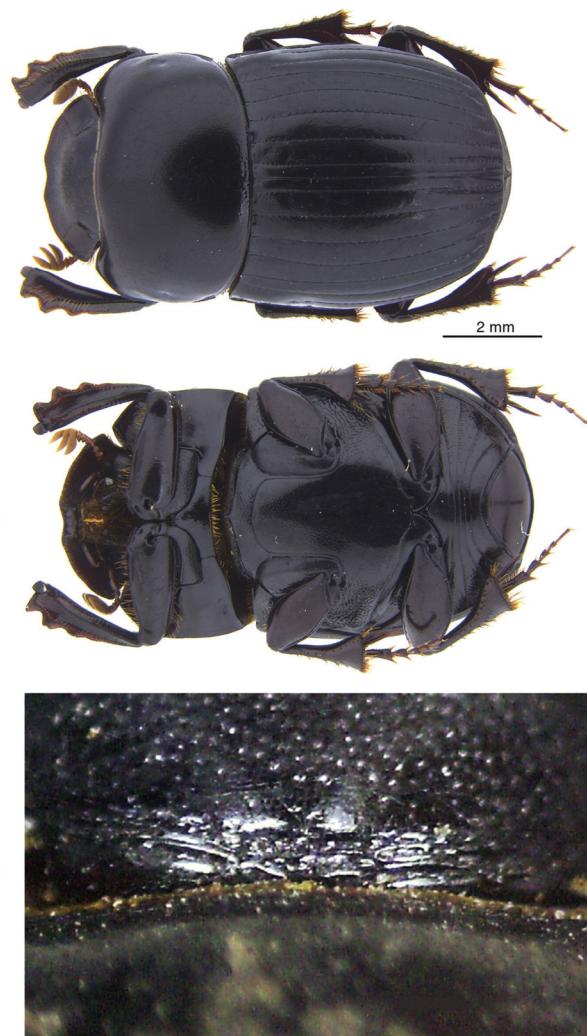

Results

Key for the identification of Ateuchus Weber from Mexico (modified from Kohlmann, 1981, 2000)

***Ateuchus tuza* Kohlmann and Vaz de Mello, sp. nov.**

(Figs. 1–4)

Type locality: MEXICO: VERACRUZ, Dos Amates (Catemaco), elev. 300–600 m (18° 29' 21" N, 95° 03' 35" W)

Diagnosis. This species is distinguished from other *Ateuchus* species by the following combination of characters: Long and slender body; dorsum glossy; clypeus bidentate; head simply convex, lacking carina or tubercle; base of the head with a small wrinkled area in the center; anterior border of pronotum continuous, posterior border of pronotum with an area of dense and coarse punctures medially; elytral lateral portion rounded; sternellum forming a carina in the middle; pygidium slightly convex, lightly shagreen, and inconspicuously punctate.

Description. Holotype male (Figs. 1–4). **Body.** Elongate (Figs. 1–2), convex dorsally (Fig. 1). **Size.** Total length 10.0 mm. Maximum width 5.5 mm. **Color.** Dark reddish brown to black, lacking metallic sheen. **Head.** Clypeal margin anteriorly broadly V-shaped (Figs. 1–2); anterior margin slightly upturned, gena and frons coarsely wrinkled, vertex coarsely punctate, base of head with a

small wrinkled area in the center (Fig. 3), eyes viewed from above six times longer than wide. **Pronotum.** Transverse, strongly convex, surface glossy; anterior pronotal margin complete; midline weakly impressed at base; pronotal surface punctate throughout, a group of coarse punctures at the center of the pronotal base (Fig. 1); lateral pronotal fossae shallow. **Elytra.** (Fig. 1). Striae fine, shallowly impressed on disk, becoming well defined and deeply impressed on apical declivity; striae punctures elongate-crenulate, slightly wider than stria, separated by 2–3 diameters on disk and apical declivity. Interstriae slightly convex on disk, surface minutely punctate throughout. **Thoracic sterna.** (Fig. 2). Proepisternum excavate anteriorly, surface of excavated portion granulate, with fine and rather long setae, bordered posteriorly by a well-defined keel. Proepimeron finely wrinkled. Sternellum glabrous and forming a keel at its center. Mesometasternal suture arched medially, marginal bead fine. Mesosternum coarsely punctured forming rugulae. Mesepisternum flat, surface-forming rugulae. Metasternum evenly convex, disk evidently punctate, surface glossy between punctures, lateral lobes forming rugulae; midline clearly impressed along three fourths of its length. **Legs.** (Figs. 1–2). Foretibia with four teeth on outer margin, the basal one weakly developed; foretibial spur expanded and truncate apically; foretibiae and forefemora long and slender; forefemur smooth, finely punctate throughout. Metatibiae obliquely truncate apically; apical spur spiniform. **Abdomen.** (Fig. 2). Sternites 3–7 crenately punctate along their anterior borders. Last abdominal segment slender. Pygidium slightly convex and lightly shagreen with indistinct punctuation; basal sulcus fine and deep throughout; marginal bead continuous. **Male genitalia.** Parameres simple, tapering to apex in lateral view, apical portion rounded in dorsal view. The internal sac of the aedeagus with three hooks, two spine-like and one spoon-like (Fig. 4).

Allotype: Female. Total length 9.5 mm. Maximum width 5.0 mm. Same as male with the following sexual differences: clypeal margin anteriorly, not so broadly V-shaped; lateral pronotal margin not arched; last abdominal segment broader medially; foretibiae and forefemora shorter and foretibial spurs slender and slightly bent at tip; pygidium not as long.

Variation: Total length 9.5–10 mm. Maximum width 5.0–5.5 mm.

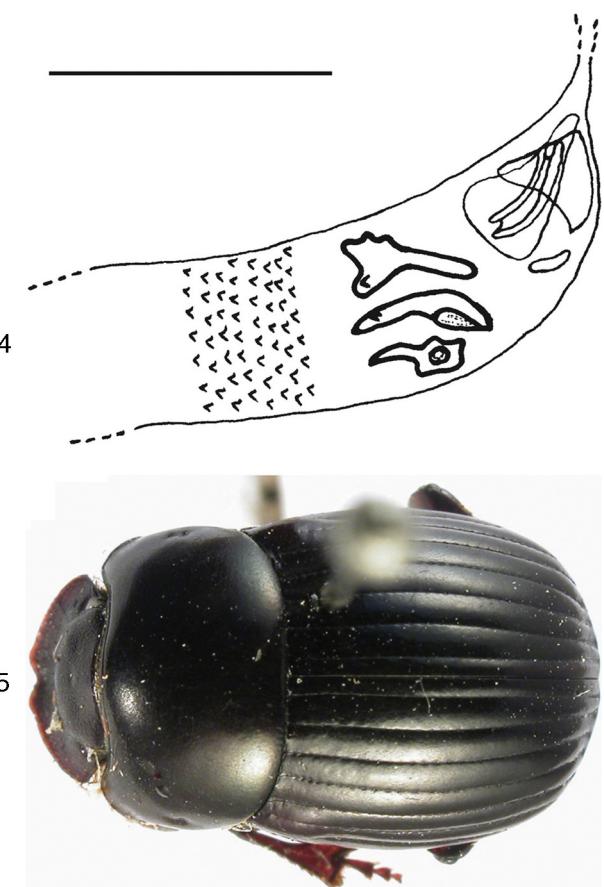

Material examined (34 specimens): **Holotype.** Male: México: Veracruz: Dos Amates (Catemaco), 8–V–1968, P. Reyes, M. Cabrera cols. Nido de tuza. Cámara de desechos (CEMT). **Allotype.** Female: *ibidem*, one female. **Paratypes.** *ibidem*, six males, four females (three males and three females at CEMT; one male, Gonzalo Halffter personal collection, Coatepec, Mexico; one male and one female at Bert Kohlmann personal collection, Las Mercedes de Guácimo, Costa Rica; one male to be deposited at Canadian Museum of Nature, Ottawa, Canada); one male, one female, Entomological Collection at the Institute of Ecology, Xalapa, Mexico (IEXA), México: Oaxaca, Sta. María Chimalapas, 12-VI-2015, colecta directa, dentro de madriguera de tuza, J. Luis S. Huerta col.; five males, seven females, *ibidem*, 16-VI-2015; two males, two females, *ibidem*, 18-VI-2015; one male, one female, *ibidem*, 19-VI-2015; two females, *ibidem*, 22-VI-2015.

Remarks: This is the first North American inquiline *Ateuchus* species collected from a pocket gopher burrow.

Etymology: The name *tuza*, a name in apposition, is the hispanized common name of the indigenous nahuatl word *tozan*, given to the beaver-looking subterranean rodent, where the new *Ateuchus* species was found.

Geographical distribution: The new species is so far only known from the locality of Dos Amates, Catemaco, in the state of Veracruz, and the locality of Santa María Chimalapas, Oaxaca, Mexico.

Habitat: The new species was collected in the waste chamber of a pocket gopher (Rodentia: Geomyidae) burrow during the month of May. Although the rodent of the original collection site was not

Figures 4–5. *A. tuza* sp. nov.; 4, drawing of the internal sac, line equals 1 mm; 5, *A. hornai* (Balthasar, 1939), dorsal habitus of the female holotype.

identified at the time, it is most likely that the specimens were found inside the nest of *Orthogeomys hispidus* (Le Conte).

Chorological affinities: Interestingly, this new *Ateuchus* species is found under similar ecological conditions, a lowland tropical area, as *Ateuchus cujuchi* Génier, the other known inquiline rodent burrow *Ateuchus* species from Bolivia (Génier, 2015). *A. cujuchi* was collected in a *Ctenomys* burrow, a rodent belonging to a different family, Ctenomyidae, as the one collected in Mexico.

Taxonomic relationships: The shape of the body of this species resembles the South American species *apicatum* (Harold, 1867) and is clearly not related to the known body shape of the North or Central American *Ateuchus* species. The new species will key to couplet 23/24 (*apicatum*) in Balthasar's (1939) key. It can be easily separated from *A. apicatum* because of the presence of the small rugose area at the center of the base of the head and the presence of coarse punctures at the middle of the pronotal base. This taxonomic relationship would suggest that *Ateuchus* species derived of South American lines have adapted to and colonized lowland gopher nests in North America; whereas, in the mountainous areas of North America it is species of the genus *Onthophagus*, which has adapted to colonizing gopher nests (Anduaga and Halffter, 1991; Lobo and Halffter, 1994; Zunino and Halffter, 2007).

This new species shows adaptations to living in an environment devoid of light, like the subterranean gopher nest. First, the dorsal eye area is very small. Second, the aforementioned rugose area at the base of the head is a stridulation mechanism, similar to those found at the base of the head of *Uroxys*, as found in *U. microcularis* Howden and Young, *U. micros* Bates and *U. platypygia* Howden and Young (Delgado and Kohlmann, 2007; Solís and Kohlmann, 2013),

and most probably helps in the communication process of this species.

New distribution records of and notes on *Ateuchus* Weber from Mexico and Central America

Ateuchus guatemalensis (Bates), 1887

This species has been recorded from Chiapas, Guatemala and Honduras. It is here recorded for the first time from Nicaragua.

Nicaragua: Jinotega: Cerro Kilambe, Camp 5, Las Torres, UTM–16P–1500283–0639500, 1200 m, 23/30-IV-2001, col. J. Sunyer y B. Hernández (5 specimens at CEMT); Masaya: Las Flores, VII–1998, col. J. Téllez (1 specimen at CEMT).

***Ateuchus hornai* (Balthasar, 1939), new combination** (valid species)
(Fig. 5)

This species was previously considered a synonym of *A. illaeum* based on the original description, since the holotype was not available for study at the time (Kohlmann, 1984). The examination of the female holotype found in the Natural History Museum in Prague, Czech Republic (Bezdek and Hajek, 2011), allowed us to consider it a valid species, distinguishable by the characters in the key presented herein. We suspect the type locality (Necaxa, Puebla, México) to be wrong, and we hope that a male will be collected in order to prepare a more thorough description of this interesting species.

Conflicts of interest

The authors declare no conflicts of interest.

Acknowledgements

We thank Dr. Vinicio Sosa from the Institute of Ecology, Xalapa, Mexico, for his information regarding the possible identity of the rodent, where the new *Ateuchus* species was collected. We also thank the Alexander von Humboldt Foundation, who most graciously donated the optical equipment used in this study, as part of the support given to the first author (B.K.), during his sabbatical stay at the Technical University of Dresden in 2010. We thank Jiri Hajek, National Museum, Prague, for the kindness of preparing the pictures of the holotype of *Choeridium hornai* that was examined by F.Z.V.M. during a sabbatical year 2013–14 granted by CNPq (202327/2013-2), with one trip to Prague funded by F.Z.V.M. is a CNPq (Conselho Nacional de Desenvolvimento Científico e Tecnológico) fellow (302997/2013-0 and 306745/2016-0) and is granted by FAPEMAT (*Fundação de Amparo à Pesquisa do Estado de Mato Grosso* (PRONEM 568005/2014) and CNPq (405697/2013-9, 440604/2015-0)).
