CHEMICAL AND BIOLOGICAL INVESTIGATIONS ON MEDICINAL PLANTS OF WEST AFRICA.

Ajibola A. Olaniyi (*)

It is an outstanding privilege to have been invited to this Symposium. Therefore, I would like first to thank all those concerned with the decision to grant me this honour on the occasion of the 8th Symposium on Medicinal Plants of Brazil.

Modern times owe much to traditional medicinal use of plant drugs than a cursory glance would reveal. Plant products have been with man through all history so that their effects be tested and scrutinized through endless trials of a hit or miss nature. It was only after the medicinal chemist had pried into the nature of the chemical secrets of the folk remedies that major drugs such as belladona, digitalis, ergot, quinine, reserpine etc., moved into prominence as reliable and immensely used drugs. The untapped vast flora of Nigeria in particular and of West Africa in general is well recognized and the conscious efforts that are being made by scientists to exploit the constituents from the plants growing in this sub-region, which have been proved traditionally to be of medicinal value have started to yield promising results.

The literature is abundant with examples of new and previously known compounds isolated from medicinal plants growing in the sub-region with little thought to the possible biological activity tied up with those novel molecules. As pointed out by Witkop, (1971), the isolation and structural elucidation of new compounds from plant materials is still just a prologue, the drama does not unfold until these "children" of nature are taken by man and are returned to participate in the dynamics of life in other systems. This paper reviews the results of research carried out on some medicinal plants growing in West Africa which have been investigated chemically and with proven biological activity. This review has been circumscribed by the condition that it should deal with natural products of proven chemical structures and showing some kind of biological activity or other. The approach adopted has been rather selective and the presentation is based on a classification according to chemical structure.

Terpenoids and Sterols

Glycoside of Oleaolic acid from Tetrapleura tetraptera (f. Mimosaceae). From the fruit of T. tetraptera oleaolic acid glycoside (I) has been isolated and shown (Adesina et al., 1979) to be responsible for the anti-convulsant properties of the plant material.

Echinocystic acid glycoside is a saponin, from Albizzia adianthifolia, family Mimo.
sacaeae. The plant is widely distributed in tropical Africa. The saponin, which was isolated from the stem bark and characterised as the aglycone, echinocystic acid (II), showed marked antibacterial activity against gram positive and some gram negative organisms (Olaniyi et al., 1976). The demonstration of the antibacterial properties of the saponin content of the plant clearly supports its use in traditional medicine as in the treatment of scabies and other skin complaints.

Sterols from *Momordica foetida*: *M. foetida* f. Cucurbitaceae is used locally to lower blood sugar. A crystalline solid characterised as a homogeneous mixture of $\beta$-sitosterol-$\beta$-glucoside (III) and 5,25-stigmasta-diene-3$\beta$-ol glucoside (IV) was isolated (Olaniyi, 1975) from the whole plant and unripe fruit and shown to lower the blood glucose levels of fasting rats over the experimental period of 18 hours comparable with that produced by insulin (Marquis et al., 1977). However, it had no appreciable effect in diabetic animals or those in which diabetes was induced. A related specie, *M. charantia* is reported to be a popular folklore remedy for diabetes mellitus in Indian (Rivera, 1940).
Macrocyclic diterpene esters from *Euphorbia kamerunica* (f. Euphorbiaceae). Plants of the genus *Euphorbia* produce ingenol and phorbol esters and these compounds are well known for both their acute and chronic toxic effects including pro-inflammatory and tumor-promoting activities (Abo & Evans, 1981). During routine testing of column fractions from *Euphorbia kamerunica* it was found that the non-polar fractions which have no pro-inflammatory activity demonstrated pronounced cytotoxic activity in vitro against mouse TLX/S lymphoma cells. Three macrocyclic diterpene ingenol esters have been isolated from the latex of *E. kamerunica* growing in Nigeria (Abo & Evans, 1981). These esters have been shown to have anti-cancer activity in in vitro tests carried out on cultured rat basophilic leukemia cells (Abo, personal communication).

**Coumarins**

The identification of vafzelin (VIII) and uvafzelin (IX) and other constituents of *Varia afzelii* (f. Annonaceae) has been reported (Hufford *et al.*, 1980). Uvafzelin, the most active constituent, was found to be active against *Staphylococcus aureus*, *Bacillus subtilis* and *Mycobacterium smegmatis* but showed no significant anti-tumor or cytotoxic activity (Hufford *et al.*, 1981).
Scopoletin from *Tetrapleura tetraptera*. *T. tetraptera*, f. Mimosaceae, is a large perennial tree growing throughout the rain forest of West Africa and is used in folkloric medicine in the management of convulsions, leprosy, inflammation and rheumatic pains. From the fruit of the plant scopoletin (X) has been isolated and characterised (Adesina & Ojewole, 1981; 1983). The cardiovascular and neuromuscular actions of scopoletin have been demonstrated in laboratory animals and the compound has been shown to possess depressor (hypotensive) effects in anaesthetized rats and produced a negative chronotropic and inotropic responses on guinea pig isolated atria. It also possessed a non-specific spasmolytic activity on smooth muscles.

Lignans

Lignans of *Justicia flava*. *J. flava*, f. Acanthaceae, a herbaceous plant which flourishes in West Africa, has abundant use in folk remedies, such as in treating rheumatism, fevers, diarrhoea, yaws and as an astringent while the powdered leaves are used in killing fish. From the acidic fraction of the methanolic extract of the leaves two known lignans isolariciresinol (XI) and helioxanthin (XII) as well as a new lignan, justicinol (XIII) were isolated and characterised (Olaniyi & Powell, 1980). Helioxanthin and justicinol were shown to be active in vitro in the P-388 lymphocytic leukemia cell culture with an $ED_{50}$ of $0.64 \times 10^{-1}$ and $< 1.0 \times 10^{-1} \mu g/ml$ respectively and were partly responsible for the anti-tumor and cytotoxic activity of *J. flava* extracts (Olaniyi & Oguntimein, 1981). Chemical studies on the methanolic extract of the root yielded two other new lignans named orosunol (XIV) and 8-demethylorosunol (XV). Both lignans showed no appreciable anticancer activity in the test system.
The plant kingdom continues to be a prospective and fruitful hunting ground for new tumour inhibitors. Although many of the compounds found to be active may never be used as drugs and hence will not be of direct value to clinical practice, it is difficult to speculate on their overall value. In some instances their toxicity precludes their use, but by studying the way in which they act against experimental cancers it is possible to learn something about the mechanism involved in cancer formation.

Piperine and derivatives from *Piper guineense*. *P. guineense*, f. Piperaceae, known as West African black pepper, occurs in many parts of West Africa, especially Ghana and Nigeria. It is used in many traditional formulations for the treatment of coughs, gastrointestinal disorders, bronchitis, venereal diseases and rheumatism and as a spice in foods. Several active constituents have been isolated from this plant by different research workers (Dwuma-Badu, 1983). Some of the constituents, piperine (XV), dihydropiperine (XVII), dihydropiperlonguminine (XVIII) and dihydrocubebin (XIX) showed antimicrobial activity against *Mycobacterium smegmatis* (ATCC 607) at a concentration of 100μg/ml while in addition, piperine exhibited antimicrobial activity against *Candida albicans* (ATCC 1023) and dihydropiperine was active against *Klebsiella pneumonia* (ATCC 1003).

### Alkaloids of Strychnos Species

*Strychnos* is a genus which is widely distributed in the tropical areas. Members of this genus are used as arrow poisons in Africa and S. America. Among the West African *Strychnos* species, (f. Loganiaceae) *S. dinklagei*, *S. afzelii*, *S. barteri*, *S. decussata* and *S. usambarensis* have been found to contain alkaloids with convulsive and muscle relaxant effects. The first isolation of a convulsive alkaloid from African *Strychnos* specie was achieved by continual pharmacological screening for convulsive and muscle relaxant effects in the East African *S. icaja* Bail, leading also to the identification of 4-hydroxystrychnine in that specie. Further screening led to the isolation of new chemical and biological investigations ...
tertiary indole alkaloids with a pronounced muscle relaxant effect and producing clonic convulsions in high doses in other species.

**Ellipticine** is the main alkaloid from *S. dinklagei* Gilg, found in W. Africa and used in local medicine in the treatment of diseases of the mouth, the kidneys and the heart. Ellipticine (XIXb) a non-corynane, strychnine-type of alkaloid from Strychnos specie (Michel et al., 1980) was shown to have slight convulsive properties (Sandberg et al., 1971; Verpoorte & Bohlin, 1976).

Akagerine and derivates: 0-methyl akagerine (XX) from *S. dinklagei* (Verpoorte & Bohlin, 1976) and *S. decussata* and 10-hydroxy-17-0-methyl akagerine (XXI) and 10-hydroxy 21-0-methylkribine (XXII) (Rolfsen et al., 1980) from *S. decussata* and the epi-isomer (XXIII) produced strychnine-like effects having both clonic and tonic convulsions.

![Structural formula of Ellipticine (XIXb)](image1)

11-methoxymacusine (XXIV) the major quaternary alkaloid from the stem and root bark of *S. angolensis* showed muscle relaxant activity with a minimum lethal dose of 100mg/kg (Verpoort et al., 1983)

![Structural formula of 11-methoxymacusine (XXIV)](image2)

Decussine and decussine-type alkaloids: A new tertiary pentacyclic indole alkaloid was isolated from *S. decussata* stem bark. The structure of the alkaloid, decussine (XXV), was determined by its spectral data and confirmed by X-ray crystallography (Rolfsen et al., 1980). A dose of 50mg/kg gave a graded response of XX in the screen grip test while
A concentration of 5.1 μg/ml (16n mole/ml) of decussine reduced the amplitude of the contraction of a rat diaphragm, elicited by electrical stimulation of the phrenic nerve to 50%; the effect was not antagonised by synstigmine (neostigmine).

Decussine, though a tertiary amine, had a pronounced muscle relaxant effect, both in vitro and in vivo on mice, thus possessing a strong action on neuro-muscular junction similar to that of tubocurarine, a quaternary ammonium salt (Rolfsen & Olaniyi, 1981). Three other tertiary indole alkaloids have also been isolated from S. decussata viz: bisnordihydrotoxiferine, 3,14-dihydrodecussine (XXVI) and 10-hydroxy-3,14-dihydrodecussine (XXVII). The latter two compounds gave weaker muscle relaxant effects compared with decussine. This observation may be explained as a possible consequence of the double bond between the C3 and C14 in (XXVI) and (XXVII) for muscle relaxant activity (Rolfsen et al., 1981).

**Quaternary alkaloids of S. decussata**

Malindine (XXVIII) is the major quaternary indole alkaloid of a novel structure, obtained from the water soluble fraction of the stem bark of S. decussata. Its structure was determined by a combination of spectral methods and its stereochemistry established by circular dichroism (CD) and Nuclear Overhauser Effect (NOE) experiments. Malindine showed muscle-relaxant effect when injected intraperitoneally in mice and also produced a 50% reduction in amplitude of the concentrations of a diaphragm-muscle preparation at a dose of 0.5 mg/ml. This compound was shown to be mainly responsible for the muscle relaxant effect of the aqueous extract of the stem bark of S. decussata (Olaniyi et al., 1981).

![Chemical structure of Malindine](image)

Other quaternary alkaloids isolated from the plant include: Macusine-B, O-methylma cusine-B and alkaloid of macusine A or C-type.

Other Alkaloids

Alkaloids of *Cryptolepis sanguinolenta*; *C. sanguinolenta* f. *Asclepiadaceae*, an important medicinal plant in West Africa, particularly Ghana, is used in traditional medicine for the treatment of malaria, wound and urinary tract infections. From the root and stem of the plant (Dwuma-Badu et al., 1978) have isolated and characterised fully two alkaloids—quindoline and cryptolepine (XXXI). Cryptolepine, the major alkaloid, has been shown to be active against gram positive and gram negative organisms as well as on rickettsia-like organisms (Dwuma-Badu, 1983). Furthermore (Bamgbose & Noamesi, 1981) have reported that the alkaloid has anti-inflammatory activity and that it inhibits prostaglandin synthesis.

![XXXI](image)

Funiferine (XXXII), a bisbenzyl isoquinoline alkaloid from *Tilicora fumifera* and *T. dinklagei* f. *Menispermaceae*, has been found to be active against acid fast growing micro-organisms (Dwuma-Badu, 1983). Funiferine has also been shown to have some activity in P-388 lymphocytic leukemia and to inhibit the growth of acid fast bacillus *Mycobacterium smegmatis* (Geran et al., 1972).

![XXXII](image)

Alkaloids of *Enantia chlorantha* or *E. polycarpa*. This plant is used traditionally in West Africa for treating ulcers, leproma spots and jaundice. The plant is reported to contain protoberberine-type alkaloids—berberine (XXXIII) and palmatine (XXXIV) (Irvine, 1961). Manske (1975) has reported that palmatine possesses anti-arrhythmic, positive inotropic adrenocorticotropic, anticholinesterase, analgesic and antibacterial action. Bamgbose and co-workers (Bamgbose et al., 1979) have also shown that an aqueous extract of this plant was able to repair or reverse the liver damage produced in experimental rabbits. This observation is significant since it lends support to justify the widespread use of this plant in Nigeria as a cure for jaundice. It is possible that the analgesic, adrenocorticotropic and antibacterial effects of the alkaloid constituents are responsible for the effective use of the plant in the treatment of jaundice.
Alkaloids of *Alstonia boonei*: *Alstonia boonei* Wild (A. congensis), f. Apocynaceae, is widely used as an antipyretic in malaria and sometimes, together with the leaves and roots, in experimental application for rheumatic pains. The main alkaloid of the bark of the plant, echitamine (XXXV), has been observed to cause a fall of the blood pressure in hypertensive cats (Kucera et al., 1973; Marquis, 1975). The drug is reported to potentiate barbiturate sleeping time of mice rats and enhanced the lethality of strychnine (Raymond Hamet, 1941).

Miscellaneous

Fagaramide from *Zanthoxylum zanthoxyloides*: The root bark of *Z. zanthoxyloides*, f. Rutaceae, is used locally in the treatment of fevers of various aetiologies and sickle cell crises. The anti-inflammatory activity of fagaramide, isolated from the plant material, has been shown (Oriowo, 1982) to be effective against carrageenan paw edema in rats and was about twenty times less potent than indomethacin, a non-steroidal anti-inflammatory agent. Fagaramide (XXXVI) is effective against the prostaglandin phase of the acute experimental inflammatory reaction. It was suggested that part of its anti-inflammatory activity is mediated via inhibition of prostaglandin synthesis.
Hydroxybenzoic acids from *Z. zanthoxyloides*. Many constituents have been isolated from the stem bark of this plant. Purification of the aqueous extract of the root resulted in an antisickling fraction which was shown by gc-ms to be a mixture of some 14 components (Sofowora et al., 1975). 2-Hydroxy-methylbenzoic acid was the only compound characterised from this fraction and it possessed antisickling activity. A patent has been awarded for the IV treatment of sickle cell disease which contains 2-hydroxy methylbenzoic acid alone or in a combination with other substituted benzenecarboxylic acids (Sofowora, 1976). Ekong and co-workers (Ekong et al., 1975) have also demonstrated that 3,4-dihydro-2,2-dimethyl-2H-1-benzopyran-6-butyric acid (XXXVII), a derivative of a natural product, xanthoxyl isolated from the roots of *Z. zanthoxyloides* showed antisickling effects in vitro.

![XXXVII](image)

Kolanone from *Garcinia kola*. *G. kola* is a large forest tree found throughout West and West Central Africa. Its seeds and chewing sticks are thought to aid oral hygiene presumably by exerting an antibacterial action in the mouth. From the light petroleum extract of the fruit pulp, a novel polyisoprenylbenzophenone named kolanone (XXXVIII) has been isolated and shown to exhibit significant antimicrobial activity against a range of organisms (Hussain et al., 1982). Kolanone is at least partially responsible for the antiseptic properties that local usage of *G. kola* implies.

![XXXVIII](image)

One of the prerequisites for the success of primary healthcare is the availability and use of suitable drugs. Plants have ever been a common source of medicaments, either in the form of traditional preparations or as pure active principles. It is gratifying to note that the successes of the past on medicinal plant research in the West African sub-region, through a more thorough and adequate scientific study and on a systematic interdisciplinary basis, are now providing the necessary stimulus and encouragement for further...
There is no doubt that natural product studies involving search for new biologically active substances will present unique challenges but one must be aware of the problems inherent in this kind of work, especially as regards obtaining appropriate funds and securing the services of co-operative pharmacologists to ensure suitable biological evaluations of crude drug extracts and isolated pure compounds. These problems are more compounded in the third world countries with very limited infrastructural, manpower and financial resources. Lack of research based pharmaceutical industries in the sub-region has contributed most adversely to the possible exploitation and utilization of results of proven investigations. Regardless of these limitations we need to press on in our efforts to pry into the frontier areas of scientific drug innovation as we must continue to identify new drugs to combat diseases, particularly those that have defied modern medical science and also we must identify new sources of existing drugs and discover new materials which could be used as precursors or templates in drug synthesis. In this way, I believe, we shall be able to make a contribution towards the development of better drugs for the control of prevalent tropical diseases which have continued to plague the developing countries.
