Twiddler Syndrome

Acácio Fernandes Cardoso e Gyovanny Mendes Almeida
Hospital Aroldo Tourinho, Montes Claros, MG - Brazil

A male 32 year old patient with Chagas’s cardiopathy was admitted presenting with ventricular fibrillation reverted after successive electrical defibrillation maneuvers. He was submitted to dual chamber cardioverter defibrillator implantation, and returned asymptomatic thirty days after hospital discharge. The threshold test showed absence of atrioventricular capture with maximum pulse energy. Physical examination revealed irregularities over the generator suggesting displacement of the electrodes (fig. 1). Chest fluoroscopy showed dislodgement of the leads, both grouped around the generator (fig. 2). Rotation of the generator, whether inadvertent or deliberate, resulting in the dislodgement of the electrodes, loss of capture or diaphragmatic stimulation is known as Twiddler Syndrome.

Key words
Chagas cardiomyopathy; desfibrillators implantable; electrodes implanted/adverse effects; Twiddler syndrome.
