Macrodactily with skin hypertrophy: a minimal form of the Proteus Syndrome*

Macrodactilia com hipertrofia da pele: uma forma mínima da síndrome de Proteu

Hiram Larangeira de Almeida Jr1
Rudolf Happle3

Abstract: The Proteus syndrome was described 1983. It has asymmetric gigantism of the limbs, verrucous epidermal naevi, cerebriform enlargement of the plantar region, vascular malformations and neoplasms, as lipomas. It received this denomination after Proteus from the Greek mythology, who had the ability to change his form. A 15 year-old boy, reported a congenital hypertrophy with syndactyly of the second and third right fingers. The second case is a 35 year-old man, who reported that since birth the second right toe was bigger than the other toes, skin hypertrophy was also observed. These cases document a localized form if the Proteus syndrome, which may widen the spectrum of its variability.

Keywords: Hypertrophy; Hand deformities; Foot deformities

INTRODUCTION

The Proteus syndrome was described by the German Pediatrician, Hans-Rudolf Wiedemann in 1983 1. It is characterized by asymmetric gigantism of the limbs, verrucous epidermal naevi, cerebriform connective tissue nevus of the plantar region, vascular malformations and neoplasms, such as lipomas 2-4. This peculiar syndrome received this denomination in comparison to Proteus from the Greek mythology, who was characterized by the ability to change his form to avoid capture.

We examined two cases of a localized form if the Proteus syndrome, which may widen the spectrum of its variability.
CASE REPORTS

The first case is a 15 year-old boy, who reported that since birth a hypertrophy with syndactyly of the second and third right fingers was observed, the fingers were separated surgically. He asks for the possibility of a surgical treatment, since he feels some embarrassment with his dysmorphic right hand. At skin examination an important macrodactily was seen (Figure 1) with some lateral deviation of the affected fingers. The hypertrophic nails were not dystrophic. The skin adjacent to the enlarged fingers was thicker than the rest of the back of the hand.

The second case is a 35 year-old man, who reported that since birth the second right toe was bigger than the other toes. The patient does not want to treat his condition. Skin examination showed hypertrophy of the second right toe (Figure 2), with adjacent enlargement of the plantar skin. The plantar dermatoglyphics were maintained in the hypertrophic skin area (Figure 2).

DISCUSSION

This multisystemic heterogeneous features were termed Proteus Syndrome, since it may be widely variable, as the Greek sea-god Proteus. The adjective derived from this name, protean, is used to denote mutant, variable, taking many forms.

The diagnosis may be established with mandatory general criteria (mosaic distribution of lesions, progressive course and sporadic occurrence) and with specific criteria, such as connective tissue nevus, or two of the following features (epidermal nevus, disproportionate growth of the limbs, skull hyperostosis, megalospondylyodysplasia, visceromegaly, bilateral ovarian cystoadenomas or parotid adenoma), or three of the following criteria (dysregulated adipose tissue - lipomas or fat absence, vascular malformations - capillary, venous or lymphatic, facial phenotype - dolichocephaly, long face, minor downslanting of palpebral comissures and/or minor ptosis, low nasal bridge, wide or anteverted nares, open mouth at rest).

The cases here described have a localized distribution of lesions and are sporadic, with a skin hypertrophy, which may be considered a connective nevus and with localized limb overgrowth, the macrodactily, therefore they fulfill general and specific criteria to establish the diagnosis of Proteus syndrome.

There are many reports in the literature of macrodactily with skin hypertrophy, affecting fingers or toes, some other cases were published as isolated macrodactily, probably before the description of the Proteus syndrome.

This minimal acral variant should be included in the spectrum of the Proteus Syndrome and should be recognized by dermatologists.
