Botulinum toxin for treating unilateral apraxia of eyelid opening in a patient with congenital myotonia

Tratamento da apraxia de abertura palpebral unilateral em portador de miotonía congênita com toxina botulínica

ABSTRACT

A 37-year-old female presented with severe apraxia of lid opening (ALO) affecting the right upper lid associated with Becker congenital myotonia (MC). The patient had a history of right upper lid ptosis for 25 years that was exacerbated over the previous month with severe incapacity to open her right eye. No other associated neurological or ophthalmic symptoms were observed. The patient was treated with botulinum toxin (BoNT-A) injection into the pretarsal and lateral canthus region of the orbicularis oculi of the affected eyelid. Treatment with BoNT-A is an effective method of managing ALO in Becker MC. This is the first case of unilateral ALO in the course of Becker MC that was successfully treated with injections of botulinum toxin.

INTRODUCTION

There are two types of myotonia congenita (MC; also congenital myotonia): Thomsen and Becker. Thomsen is autosomal recessive and is characterized by muscle stiffness present since early childhood or with onset in the third or fourth decade of life. All striated muscle groups may be involved[1].

Apraxia of lid opening (ALO) is the inability to open the eyes after voluntary closure of the eyelids. ALO can interfere with normal lid opening, which results in significant vision interference and adversely affects activities of daily living. The condition has been described as a bilateral phenomenon related to multiple causes[2-4]. We present a case of unilateral Becker MC associated with unilateral ALO that was successfully treated with botulinum toxin (BoNT-A).

CASE REPORT

A 37-year-old Caucasian female presented with a 25-year history of unilateral right upper lid ptosis diagnosed by a neurologist as Becker MC. The patient’s older brother had MC, which was confirmed by chloride voltage-gated channel 1 positivity. The ptosis was worse in the mornings and varied over the day. The condition was controlled, had remained stable for the previous 25 years, and the patient had an acceptable quality of life. Three weeks prior to presentation, she developed progressive worsening of her right upper lid ptosis. The patient was taking cyproterone acetate, ethinylestradiol (Diane; Bayer Hispania S.L., Barcelona, Spain) to treat a deficiency of coagulation factor VII, diazepam 5 mg (Laboratorios Normon, Madrid, Spain) and sertralina 100 mg (Laboratorios Alter S.A., Madrid, Spain).

On examination, best corrected visual acuity was 20/20 in both eyes. The palpebral fissure opening was 1 mm for the right eye (OD) and 9 mm for the left eye (OS). Full extracocular motility and pupils were normal. The margin reflex distance OD was -4 mm and 3 mm OS, and levator function was 12 OD and 15 mm OS. The right orbicularis muscle maintained contraction in the right upper and lower eyelid, and voluntary opening of the OD was impaired throughout the day. The closure function of the orbicularis was normal. The patient stated that the condition disrupted activities of daily living, such as driving, going out alone, and reading on the computer, all of which decreased her quality of life (Figure 1 A).

Neurological examination indicated abnormal movements that affected the upper lid unilaterally, and all other facial movements and sensitivity were normal with no aberrant regeneration and no blepharospasm. Interestingly OS was normal. Systemically, there was mild generalized muscle hypertrophy, and phonation and swallowing were normal.

The patient was treated with botulinum neurotoxin type-A (BoNT-A; Botox®, Allergan plc., Dublin, Ireland). One hundred units of dry Botox® were diluted with 2 mL of non-preserved saline solution. We used a total of 12 units (IU). Two IUs were delivered per loci at two points of the pretarsal orbicularis in the upper right lid and 4 IU per loci were delivered subcutaneously at two points in the lateral canthus (Figure 1 B).

At the 1-week and 5-month follow-up, there was a sustained satisfactory palpebral aperture opening of 7 mm and 9 mm, respectively. There were no complications during the 5 months of follow-up. The patient is seen at follow-up examinations every 5 months, and injections are delivered as required. To date, the patient has been followed for 6 years with good outcomes and no adverse events.

DISCUSSION

Treatment for ALO with BoNT-A was used to decrease the activity of the orbicularis oculi to improve lid opening. Although there is a greater preponderance of males who are affected by MC, our patient was female(5). Onset of variable upper lid ptosis OD occurred when she was 12 years old and was concurrent with onset of puberty, which was diagnosed as Becker MC. Symptoms can be augmented during puberty, pregnancy, menstruation, hypothyroidism, and stress or in cold environments(5).

Additionally, individuals with Becker MC experience bilateral muscle stiffness, which can be observed in almost every facial muscle, the tongue, and extraocular muscles. The patient in this case had isolated abnormal movements that only affected the upper lid unilaterally. Patients with MC typically present other signs, including variable muscle hypertrophy, which is usually expressed in the neck and upper limb region, or generalized hypertrophy as in our case(5). Our patient complained of daily fluctuation of ptosis, which was worse in the morning and varied throughout the day, over 25 years. At her first examination at our facility, she reported a recent and sudden worsening of ptosis and an inability to open her lids properly. She was diagnosed as having ALO associated with Becker MC of the same (right) upper lid.

ALO may also occur, as observed in our patient who had no other abnormality of movement. ALO usually occurs more commonly in association with essential blepharospasm and extrapyramidal diseases, such as Parkinson’s disease and progressive supranuclear palsy(5-6). Some individuals with MC report painful muscular contractions, and sporadic muscle weakness.(5) However, these symptoms were absent in our patient, who was under systemic treatment to decrease muscle contraction. However, the apraxia did not improve. Hence, we elected to treat ALO with BoNT-A. A similar case of MC, ALO, and bone dysplasia treated with BoNT-A that resulted in a good outcome has been reported(7).

In conclusion, we experienced a rare case of Becker MC associated with ALO. This case was unique because of the patient’s relatively young age and the unilaterality of presentation. We believe that treatment with BoNT-A can be useful.
