Inhibition of rats extramedullary liver erythropoiesis by hyperbaric oxygen therapy

Inibição da eritropoese extramedular hepática pela oxigenoterapia hiperbárica

ABSTRACT

Purpose: To research the hyperbaric oxygen therapy effects on rats’ livers and spleens. Methods: 30 adult male Hotzman rats were used, being randomly distributed, by raffle, into 2 groups of 15 animals each: group 1 – control; group 2 – hyperbaric oxygen therapy. Group-2 animals underwent hyperbaric oxygen therapy for 120 minutes daily, 90 minutes of which were under pressure of 2.5 atmospheres. The first and last 15 minutes were used for gradual compression and decompression, respectively, for 20 days in a row. The livers and spleens of the animals from the two groups were taken out for histologic examination, on the day after the end of hyperbaric oxygen therapy in group 2 animals. Liver and spleen histologic changes of the animals from the two groups were compared by using Fisher exact test. P < 0.05 was regarded as a significant difference. Results: The only change in liver and spleen histology was the significant reduction in hepatic extramedullary erythropoiesis in the animals that underwent hyperbaric oxygen therapy (p < 0.05). Conclusion: Hyperbaric oxygen therapy reduces hepatic extramedullary erythropoiesis in rats and doesn’t jeopardize the other liver and spleen structures. Key words: Hyperbaric oxygen. Erythropoiesis. Liver.

RESUMO

Objetivo: Pesquisar os efeitos da oxigenoterapia hiperbárica sobre o fígado e baço de ratos. Métodos: Foram utilizados 30 animais machos adultos da espécie Holtzman, distribuídos aleatoriamente e por sorteio em dois grupos de 15 animais cada, assim designados: grupo 1 – controle; grupo 2 - oxigenoterapia hiperbárica. Os animais do grupo 2 foram submetidos à oxigenoterapia hiperbárica por 120 minutos ao dia, sendo 90 minutos sob pressão de 2,5 atmosferas e 15 minutos iniciais e finais para a compressão e decompressão gradativa, respectivamente, em 20 dias consecutivos. Os fígados e baços dos animais dos dois grupos foram retirados para exame histológico, no dia seguinte após o término da oxigenoterapia hiperbárica nos animais do grupo 2. Compararam-se as alterações na histologia do fígado e baço entre os animais dos dois grupos empregando-se o teste exato de Fisher, considerando diferença significante o valor de p<0,05. Resultados: A única alteração na histologia dos fígados e baços foi a redução significativa da eritropoiese extramedular hepática nos animais submetidos a oxigenoterapia hiperbárica. (p < 0,05) Conclusão: A oxigenoterapia hiperbárica reduz a eritropoiese extramedular hepática em ratos e não compromete as demais estruturas do fígado e do baço. Descritores: Oxigenação hiperbárica. Eritropoiese. Fígado.
Introduction

Hyperbaric oxygen therapy has been able to improve the evolution of animals and human beings with several diseases, in the physiopathologies of which there is triad, hypoxia, ischemia and reperfusion. Its applyance and indication in the treatment of several diseases are scientifically assured. It can even be used with specific diseases, like peripheral vascular diseases (1-4). Nevertheless, there is a vast field in the medical area in which its usefulness and unfavorable effects are still unknown, and this stimulates clinical and experimental studies, controlled in vitro or in vivo to evaluate the desirable effects and the possible complications (2; 5-9). This study aimed to research hyperbaric oxygen therapy effects on rats’ livers and spleens, through histologic analysis.

Methods

This study respected COBEA’s (Brazilian College of Animal Experimentation) ethical principles and was approved by the Federal University of Minas Gerais (UFMG) Medicine School Surgery Department Departmental Chamber. 30 male Holtzman rats were used in the study – They were kept in appropriate cages, exposed to light in regular cycles of 12 hours and fed with industrial feed (Nuvilab CR®, Nuvital Laboratory and ad libitum water in all phases of the study. The animals were randomly distributed, by raffle, in two groups:

1. Group 1 – Control – 15 animals that didn’t undergo procedures;

2. Group 2 – Hyperbaric oxygen therapy – 15 animals that underwent hyperbaric oxygen therapy.

Hyperbaric oxygen therapy

The one-patient hyperbaric chamber (model BLKS 303 MK, Moscow) approved for use in Brazil by the National Agency of Sanitary Watch was utilized. Hyperbaric oxygen therapy was applied to Group 2 animals, using oxygen at 100% under pressure of 2.5 atmospheres, for 90 minutes, for 20 days in a row with regular intervals of 24 hours. The total duration of each session was of 120 minutes, as 15 minutes were used for gradual compression and 15 minutes were used for gradual decompression.

Death of animals and removal of organs

Groups 1 and 2 animals were killed by ether inhalation, 24 hours after the end of hyperbaric oxygen therapy, which the animals from group 2 underwent. Livers and spleens were removed after the separation of vascular pedicles and adjacent ligaments. Those organs were manually washed in current water until blood ran off; they were then fixed in formaldehyde 10%.

Histologic analysis

Livers and spleens were processed in paraffin blocks, longitudinally sliced in microtome gauged for 5µm and stained with hematoxylin and eosin, by the use of light microscopy. Liver and spleen histologic changes like thrombosis in hepatic, portal and centrilobular veins, hepatocytes necrosis, changes in Kupffer cells, hepatic extramedullary erythropoiesis, red pulp congestion and hemosiderosis were researched.

Studied variables

Liver and spleen histologic changes of the group of animals that underwent hyperbaric oxygen therapy were compared with the control group by using Fisher Exact Test, considering a significance level of 5% ($p < 0.05$).

Results

The histologic study of livers and spleens of the animals that underwent hyperbaric oxygen therapy (group 2) showed a significant reduction of hepatic extramedullary erythropoiesis in comparison with the control group (group 1) ($p < 0.05$) 2 (Table 1 and Figures 1 e 2). The other changes that were researched weren’t found.

Note: $p < 0.001$ ($p$ value refers to Fisher exact test)
Experience with hyperbaric oxygen therapy in Brazil started in Rio de Janeiro with Álvaro Ozório in 1940, in the treatment of patients with soft parts infection\(^7\). Hyperbaric oxygen therapy consists of intermittent inhalation of oxygen at 100%, with a pressure of over one atmosphere. The current protocols recommend the implementation of 120-minute sessions and pressure between two and three atmospheres. Higher pressures are necessary in the treatment of decompressive disease and air embolias, reaching six atmospheres\(^5\)-\(^10\). The main hyperbaric oxygen therapy favorable effects are the following:

- a bigger input of oxygen to hypotoxic tissues;
- reactivation of humoral and cellular activity (macrophages, plasmacytes, fibroblasts, osteoclasts);
- stimulus to angiogenesis, with formation of granulation tissues; potentionial of some kinds of antibiotics and reduction in cicatization time\(^5\)-\(^7\).

The main hyperbaric oxygen therapy complications described are: pneumothorax, otitis media, gasous embolia, ocular fibrioplasia and transitory reduction of pulmonary expiratory capability, which are related to secondary effects in organs and tissues that are susceptible to intracavitary pressure differences.

Although harmful effects of this therapy on human viscera haven’t been described, the exposition to high pressures of O\(_2\) for a long period of time may decrease central nervous system threshold and cause convulsive crises. So the exposition to O\(_2\) at the pressure of 2.5 atmospheres in intermittent sessions of 90 to 120 minutes was defined as the ideal pattern. Complications to fetuses of experimentation animals and of humans due to the use of hyperbaric oxygen therapy weren’t observed either\(^5,8,12,13\). The Federal Medicine Council, in a publication in the Union Official Journal – 1995 – regulated the use of hyperbaric oxygen therapy as a therapeutic procedure with scientific bases and clinical indications that are at the doctor’s exclusive discretion in the following diseases: decompressive disease (usually divers’); gasous embolia; traumatic embolias by the air; serious intoxications by carbon monoxide or smoke inhalation; cyanide or hydrocyanic by product poisoning; gasous gangrene; Fournier syndrome; cellulites; fasciitises; myositises; traumatic acute ischamias; compartmental syndrome; docked extremities reimplantation; acute vasculitides of allergic or medicamentosus etiology or caused by arachnida, ophidia and insects toxins; electric and thermal burns;
refractory lesions, such as skin ulcers; decubitus eschars; auto-immune vasculitides; suture dehiscences; lesions on the skin caused by irradiation, osteomyelitides, acute anemia, in cases of blood transfusion impossibility and cerebral abscess\(^\text{(7,8,14)}\). However, further researches are necessary in order to evaluate oxygen therapy validity for other diseases and the side effects of this therapeutics\(^\text{(9)}\). Hyperbaric oxygen therapy has also been used in several animal research models, with expressive results in various diseases\(^\text{(2-4)}\). Using this therapy with rats that underwent hepatic vein ligature, It was noticed a reduction in the animals’ mortality and a significant attenuation of deleterious effects on liver and spleen, assessed by histology\(^\text{(11)}\). Erythropoiesis is by definition the process in which red cells are produced by bone marrow. In human beings, primitive red cells production happens in vitelline sac during embryonic phase but is transferred to liver during the first gestation trimester. Meanwhile, a smaller amount of erythrocytes is created in spleen and lymphatic nodes. In gestation final phase and after birth, erythrocytes are produced solely by bone marrow, although there are in liver small areas that are able to perform erythropoiesis. Extramedullary erythropoiesis isn’t exclusive to human beings. It was observed in rats and other smaller mammals. All situations that decrease the oxygen amount usually transported to tissues, for instance anemia, longstanding cardiac insufficiency, bronchopulmonary diseases (emphysema, bronchitis, arteriovenous derivations) and staying at high altitudes increase erythrocyte production speed\(^\text{(15-17,18)}\). Hypoxia is a fundamental stimulus to erythropoiesis, but without a direct action on bone marrow. Stimulus is indirect, through the production of erythropoietin, which is a floating hormone from the marrow. Stimulus is indirect, through the production of erythropoietin, which is a floating hormone from the marrow. Hyperbaric oxygen therapy caused a hepatic extramedullar erythropoiesis decrease, without changing the other liver and spleen structures.

**Conclusion**

Hyperbaric oxygen therapy caused a hepatic extramedullar erythropoiesis decrease, without changing the other liver and spleen structures.
