ABSTRACT

PURPOSE: To investigate the protective effect of dexmedetomidine (Dex) on testicular damage induced by ischemia-reperfusion injury in rats.

METHODS: Sham group underwent left scrotal exploration only (group 1). The ischemia-reperfusion only group underwent left testicular torsion and detorsion (group 2). The ischemia-reperfusion plus Dex group underwent left testicular torsion, received 50 µg/kg Dex (group 3) and 100 µg/kg Dex (group 4) intraperitoneally at minute 180 of ischemia and then underwent detorsion. We determined histopathological findings and performed specific biochemical analyses.

RESULTS: Increasing doses of Dex significantly increased TAS, and significantly decreased OSI. Analyzing the antioxidant effects of increasing doses of Dex in torsion and contralateral testicles: Dex 100 µg/kg statistically significant increased the tissue total antioxidant status (TAS) and oxidative stress index (OSI) when compared with Dex 50 µg/kg but not found significantly change on the tissue total oxidant status (TOS). However, Dex did not significantly improve these histological alterations.

CONCLUSION: The antioxidant effects of dexmedetomidine on testicular ischemia-reperfusion injury in ipsilateral and contralateral testis, but in the histopathological level, there was no difference statistically according to Johnsen’s scoring system between groups at both sides.

The antioxidant effect of dexmedetomidine on testicular ischemia-reperfusion injury

Introduction

Testicular torsion is a urologic emergency that observes commonly in the neonatal and adolescent period and is a pathological condition which reveals with testicular ischemia and surgery is generally required to restore blood flow. Testicular recovery requires early reestablishment of blood flow. Although reperfusion is absolutely necessary for the survival of ischemic tissue, reperfusion damage eventuates by generation of reactive oxygen species (ROS) on resumption of blood flow. The basic pathological mechanisms underlying ischemia-reperfusion injury (IRI) of the tissue has not yet been exactly understood. On the other hand, this oxidative stress is associated with an imbalance between cellular antioxidative systems and ROS. As a consequence of the reperfusion of the ischemic tissue, toxic-free oxygen radicals, such as nitric oxide (NO−), superoxide anions (O2−), hydrogen peroxide (H2O2), and hydroxyl radicals (OH−) are released. Moreover, in cases where repeated succession of IRI in testicular cells cause many biochemical and morphological changes which may lead to lipid peroxidation, protein denaturation, DNA damage and apoptosis.

Dexmedetomidine (Dex), a selective and potent α2-adrenocceptor agonist, was approved by the U.S Food and Drug Administration in 1999 for sedation of patients hospitalized in intensive care settings. Since then, a growing number of research articles have emerged reporting other possible indications, such as regional and general anesthesia. In addition to sedative and analgesic effects, organ-protective effects of Dex have been shown in several inflammatory models, including IRI.

Due of the antioxidative properties of Dex, it seems possible that using Dex before ischemia/reperfusion may protect the testis tissue against oxidative I/R injury. To the best of our knowledge, there has been such a report in the literature. In the present study, we therefore tried to determine whether different doses of Dex could prevent in vivo rat model of torsione/detorsione testis and contralateral testis injury-induced by I/R by measuring oxidant parameters, such as total oxidative status (TOS), oxidative stress index (OSI), and antioxidative parameters such as total antioxidant capacity (TAS) in the torsione testis and contralateral testis tissue. We also examined histopathological alterations in the tissue. Another object of the study was to evaluate the effect of different doses of Dex on contralateral testicular histology following unilateral testicular torsion. On the other hand, of course, to find a drug that can be used clinically have a great importance to reduce testicular damage of the testicles before reperfusion period.

Methods

Local ethics committee approval was obtained. Six-month-old Wistar albino male rats weighing 250-300 g were used in the study. During investigation, rats were housed at an ambient temperature of 22 °C, with a light cycle of 12-hours of light and 12-hours of dark, and 40%-70% humidity. Rats were fed pellet rat feed and tap water.

Before interventional procedures, ketamine HCl (90 mg/kg) and xylazine (10 mg/kg) were administered intramuscularly for general anesthesia.

Rats were randomized into 4 groups: group 1 = Sham (n=8), group 2 = I/R (n=8), and group 3= I/R + Dex 50 µg/kg (n=8), group 4 = I/R + Dex 100 µg/kg (n=8).

For group 1 (Sham), the left testis was accessed by scrotal incision and dissected. The scrotum was then closed with 5/0 silk suture without carrying out any procedure.

For group 2 (I/R), the left testis was accessed by scrotal incision and dissected. The testis was torse 720 counter clockwise and fixed to the wall of the scrotum with 5/0 silk suture. The scrotum was closed with 5/0 silk with the testis torse. The testis was detorsioned after 4 hours of torsion. The scrotum was closed again with 5/0 silk.

For group 3 (I/R + Dex 50 µg/kg), in addition to the procedures carried out in group 2, 50 µg/kg of Dex was administered intraperitoneally (i.p.) to each rat 60 minutes before detorsion.

For group 4 ((I/R + Dex 100 µg/kg), in addition to the procedures carried out in group 2, 100 µg/kg of Dex was administered intraperitoneally (i.p.) to each rat 60 minutes before detorsion.

Six hours after initiation of the experimental procedure, the left and right testes of rats in all 4 groups were removed for histological and biochemical measurements examination.

Histological evaluation

Testis tissues were fixed with 10% neutral formalin and parafin blocks were obtained by a routine procedure. Sections obtained from these blocks were subjected to hematoxylin and eosin staining. A light microscope with camera attachment (Olympus DP 71; Olympus, Tokyo, Japan) was used for evaluation. The tissues were examined under a light microscope and the microscopic scoring was graded on a scale of mild (+), moderate (++) and severe (+++). Spermatogenesis was assessed histopathologically using Johnsen’s mean testicular biopsy score.

Acta Cirúrgica Brasileira - Vol. 30 (6) 2015 - 415
(MTBS) criteria\textsuperscript{10}. Tubuli in 10 consecutive x400 field areas were scored and mean values were determined. The Johnsen score is based on the premise that with testicular damage there is successive disappearance of the most mature cell type, with progressive degeneration of germinal epithelium, with the disappearance of spermatooza and spermatids, then spermatocytes and finally Sertoli cells, in that order. A score of 1 to 10 was given to each tubule according to the maturity of the germ cells: A score of 1 indicated no seminiferous epithelial cells and tubular sclerosis. A score of 2 indicated no germ cells, only Sertoli cells. A score of 3 indicated spermatogonia only. A score of 4 indicated no spermatids, few spermatocytes, and arrest of spermatogenesis at the primary spermatocyte stage. A score of 5 indicated no spermatids and many spermatocytes. A score of 6 indicated no late spermatids, few early spermatids, arrest of spermatogenesis at the spermatid stage, and disturbance of spermatid differentiation. A score of 7 indicated no late spermatids and many early spermatids. A score of 8 indicated few late spermatids. A score of 9 indicated many late spermatids and disorganized tubular epithelium. A score of 10 indicated full spermatogenesis. All histologic evaluations were performed by an experienced pathologist.

**Biochemical evaluation**

Blood samples were obtained after suitable centrifugation and samples were stored frozen at -80 °C until day of analysis.

Measurement of Total Antioxidant Status (TAS) level was determined using a method developed by Erel\textsuperscript{11}. Tissue TAS levels were calculated in mmol Trolox equivalent/L. Measurement of Total Oxidant Status (TOS) levels were determined using method as previously described by Erel. Tissue TOS levels were calculated in μmol H2O2 equivalent/L. TOS levels of all tissues were determined using a novel automated measurement method, developed by Erel\textsuperscript{12}. In this method, oxidants present in the sample oxidize the ferrous ion–o-dianisidine complex to ferric ion. The oxidation reaction is enhanced by glycerol molecules, which are abundantly present in the reaction medium. The ferric ion makes a colored complex with xylene orange in an acidic medium. The color intensity, which can be measured spectrophotometrically, is related to the total amount of oxidant molecules present in the sample. The assay is calibrated with hydrogen peroxide, and the results are expressed in terms of micromolar hydrogen peroxide equivalent per gram protein (micromoles H$_2$O$_2$ equivalents per gram protein).

**Calculation of Oxidative stress index (OSI):** The TOS:TAS ratio was used as the OSI. To perform the calculation, the unit of TAS, mmol Trolox equivalent/L, was converted to μmol Trolox equivalent/L, and OSI was calculated as follows:

\[ \text{OSI} = \frac{[(\text{TOS, μmol H}_2\text{O}_2 \text{ equivalent/L})/(\text{TAS, μmol Trolox equivalent/L})] \times 100}\]

**Statistical analysis**

All statistical analysis was performed using SPSS version 15.0 (SPSS; Chicago, IL, USA). The normally distributed data are presented as mean ± standard deviation (SD) and non-normally distributed data are expressed as median (25% - 75%). Student t and One way ANOVA test with Bonferroni adjustment were used for comparing normally distributed data. Mann Whitney U and Kruskal Wallis test with Bonferroni adjustment were used for comparing non-normally distributed data. Subsequently, the relation between these parameters was evaluated using linear regression analysis (Backward). A p<0.05 was accepted as statistically significant.

**Results**

The ipsilateral and contralateral testis median TAS, TOS, OSI levels are presented on Tables I and II. Median ipsilateral testis TAS levels were respectively, 1.81 (0.83-4.75) in group 1, 1.01 (0.27-2.19) in group 2, 9.22 (8.48-10.07) in group 3 and 9.77 (8.21-10.31) in group 4. There were significant differences between groups 1 and 2 (p<0.001), 1 and 3 (p<0.001), 1 and 4 (p<0.001), 2 and 3 (p<0.001), 2 and 4 (p<0.001), and 3 and 4 (p<0.001) in terms of tissue TAS levels. Median TOS levels were respectively, 1.65 (0.49-2.78) in group 1, 1.14 (0.72-3.25) in group 2, 1.51 (1.27-1.63) in group 3 and 1.47 (0.94-2.81) in group 4. There were non significant differences between all groups. Median OSI levels were respectively, 1.35 (0.40-1.77) in group 1, 0.97 (0.68-3.30) in group 2, 0.17 (0.12-0.18) in group 3 and 0.15 (0.08-0.39) in group 4. There were non significant differences between all groups. Median OSI levels were respectively, 1.35 (0.40-1.77) in group 1, 0.97 (0.68-3.30) in group 2, 0.17 (0.12-0.18) in group 3 and 0.15 (0.08-0.39) in group 4. There were significant differences between groups 1 and 2 (p<0.001), 1 and 3 (p<0.001), 1 and 4 (p<0.001), 2 and 3 (p<0.001), 2 and 4 (p<0.001), and 3 and 4 (p<0.001) in terms of tissue OSI levels (Table 1).
Median contralateral testis TAS levels were respectively, 1.81 (0.83-4.75) in group 1, 1.24 (0.40-2.16) in group 2 right testis, 3.07 (1.34-3.68) in group 3 right testis and 7.88 (7.18-8.65) in group 4 right testis. There were significant differences between groups 1 and 2 right testis (p<0.001), 1 and 3 right testis (p<0.001), 1 and 4 right testis (p<0.001), 2 and 3 right testis (p<0.001), 2 and 4 right testis (p<0.001), and 3 and 4 right testis (p<0.001) in terms of tissue TAS levels. Median contralateral testis TOS levels were respectively, 1.65 (0.49-2.78) in group 1, 1.72 (1.62-2.88) in group 2 right testis, 2.38 (1.57-2.89) in group 3 right testis and 1.53 (1.07-1.83) in group 4 right testis. There were non significant differences between all groups. Median contralateral testis OSI levels were respectively, 1.35 (0.40-1.77) in group 1, 1.09 (0.78-7.27) in group 2 right testis, 0.75 (0.60-1.45) in group 3 right testis and 0.18 (0.12-0.24) in group 4 right testis. There were significant differences between groups 1 and 2 right testis (p<0.001), 1 and 3 right testis (p<0.001), 1 and 4 right testis (p<0.001), 2 and 4 right testis (p<0.001), and 3 and 4 right testis (p<0.001) in terms of tissue OSI levels (Table 2).

The antioxidant effect of dexmedetomidine on testicular ischemia-reperfusion injury

Discussion

Testicular torsion is still an important factor in male infertility. Contributing factors, such as formation of free radicals and lipid peroxidation, are associated with testicular ischemia. As mentioned previously, ischemia occurring due to testicular torsion and reperfusion with detorsion of the twisted testicle can lead to various biochemical and morphological changes in the testicular tissue. Furthermore, post-ischemic reperfusion causes a further increase in the tissue damage and apoptosis.8

The general concept that testicular damage caused by a transient ischemia is associated with oxidative stress is supported by the rapid induction of lipid peroxidation and the accompanying suppression of endogenous antioxidant activities such as SOD, catalase and glutathione peroxidase. On the other hand, the tissue injury induced by testicular T/D can be dramatically mitigated by pretreatment with exogenous antioxidants such as selenium.13

Although the exact mechanism of Dex in preventing I/R injury has not been elucidated, there are some opinions about this drug how exhibits its preventive properties for I/R injury. Sympatholysis is one of Dex’s properties as a result of its effect via presynaptic α-adrenoceptors. By this effect, it is suggested that Dex reduces noradrenaline release that is induced by ischemia. The reduction of noradrenaline release in the circulation by Dex may prevent potential destructive effects caused by noradrenaline by means of preventing increased free oxygen radicals production.15 A further location of α-2 receptors are on blood vessels and vasoconstriction effect of Dex is due to the influence of α-2 agonists. Maier et al.16 suggested that Dex may improve perfusion of ischemic tissue by increasing vascular resistance to non-ischemic tissue “reverse steal effect,” and hence decreases in blood flow may help to prevent the reperfusion injury caused by free radical formation and lipid peroxidation.

In the studies related to the anti-inflammatory effect of Dex in different tissues, Taniguchi et al.17 showed that Dex had an inhibitory effect on inflammatory response in lungs during endotoxemia in rats. Can et al.18 also reported the anti-inflammatory effect of Dex in spinal cord injury. In contrast, Nishina et al.19 declared that Dex had no influence on neutrophil functions in vitro. The protective effect of Dex was examined in many different tissues with different doses in many experimental studies. A previous study showed that the administration of Dex after the I/R period may produce no beneficial effect. However, when Dex was used preoperatively, it was proved to be more effective against I/R damage.20 In our study, we have applied to the subjects of Dex i.p. 60 minutes before from the detorsion.

In an experimental study, Kocoglu et al.21 demonstrated that Dex can reduce the renal injury caused by I/R of the kidney and concluded that Dex may be useful in enhancing the tolerance of the kidney against ischemia. Similarly, Gu et al.22 showed that pre or posttreatment with Dex provided cytoprotection and improved tubular architecture and function after renal ischemia. However, Billings et al.23 determined that the α-2-adrenergic receptor agonists Dex and clonidine protect mice against radiocontrast-induced nephropathy by preserving outer medullary renal blood flow. In another study, Marangoni et al.24 evaluated the effects of Dex on renal function and histology after acute hemorrhage in rats and concluded that Dex results in a better renal function but higher tubular dilation scores after acute hemorrhage. Similarly, Villal et al.25 investigated the effects of Dex on the renal system and on vasopressin plasma levels in anesthetized dogs and found that low doses of Dex can protect kidneys during ischemia by inhibiting vasopressin secretion and leading to aqueous diuresis. Our results in the present study on testicular T/D-induced I/R injury are in accordance with the previous studies for the protective effects of Dex on renal tissue. However, Curtis et al.26 noted that ketamine plus I/R injury was damaging to rat kidneys, according to histological changes, and Dex may not have completely protected the kidneys from these injuries.

Oxidative stress, resulting in an imbalance between the production of free oxygen radicals and antioxidant capacity, leads to damage of biological macromolecules and disruption of normal metabolism and physiology.27 Reactive oxygen species (ROS) can attack the polyunsaturated fatty acid in the biological membranes and induce free radical chain reactions, leading to the enhancement of lipid peroxidation.28 The methods used for the determination of oxidative stress are generally of board range. An often used and easily detectable parameter for the serum anti-oxidative and oxidant properties are the total antioxidant status (TAS) and total oxidant status (TOS)11,12. In our study, TAS, TOS and OSI parameters and histopathological changes were examined to evaluate the antioxidant capacity of increasing doses of Dex in a model of testicular torsion. Analyzing the antioxidant effects of increasing doses of Dex: In torsion and contralateral testicles, Dex 100 μg/kg statistically significantly increases the tissue TAS and OSI when compared with Dex 50 μg/kg but has not been found significantly change on the tissue TOS. In the present study, we preferred to measure oxidants and antioxidant capacity simultaneously to evaluate oxidative stress more clearly and we measured oxidative stress with OSI which was detected using both oxidative and antioxidative parameters. We evaluated TAS which reflects the antioxidative status and TOS to investigate oxidative
status using a more recently developed measurement methods by Erel. In the testicular tissue, MTBS is used to assess histopathological damage. It is based on the evaluation of progressive degeneration of the germinal epithelium. When the structure of the testis was histopathologically examined, it was observed that the histological appearance of testicular tissues of group 1 was normal. There were some histopathological changes such as degeneration, desquamation, disorganization in germinal cells, interstitial edema and capillary congestion and hemorrhage in the ipsilateral and contralateral tests of rats in group 2. These histopathological changes were also present to a similar extent in ipsilateral and contralateral tests of rats from group 3,4. However, these histopathological changes were not significantly obvious in group 3,4. In the present study, in Johnsen’s scoring system, statistically significant change has not been observed that despite application of the increasing treatment doses of Dex.

This study may support the other researches, which has been shown that ipsilateral testicular torsion causes a decrease not only in the ipsilateral torted but also in the contralateral nortorted testicular perfusion. Similar to Hanci et al. report, tissue TAS levels in administration of increasing treatment doses of Dex group were significantly higher than in groups I/R and sham but no difference showed in histological level. The absence of antioxidant effect in the histopathological tissue can be explained by when significant increase of tissue OSI value considered with the absence of decreased tissue TOS value. We suggest that the effects of Dex might be seen as more long-term administration of i.v. infusions rather then i.p. may be useful in the histopathologic level.

This prospective experimental study has some pitfall. This study could not be supported by immunohistochemical and electron microscopic findings.

Conclusion

The antioxidant effects of dexmedetomidine on testicular ischemia-reperfusion injury in ipsilateral and contralateral tests, but in the histopathological level, there was no difference statistically according to Johnsen’s scoring system between groups at both sides.
