Influence of remote ischemic conditioning and tramadol hydrochloride on oxidative stress in kidney ischemia/reperfusion injury in rats

Abstract

Purpose: To evaluate the effects of tramadol hydrochloride associated to remote ischemic perconditioning on oxidative stress.

Methods: Twenty five male rats (Wistar) underwent right nephrectomy and were distributed into five groups: Sham group (S); Ischemia/Reperfusion group (I/R) with 30 minutes of renal ischemia; Remote ischemic perconditioning group (Per) with three cycles of 10 minutes of I/R performed during kidney ischemia; Tramadol group (T) treated with tramadol hydrochloride (40mg/kg); remote ischemic perconditioning + Tramadol group (Per+T) with both treatments. Oxidative stress was assessed after 24 hours of reperfusion.

Results: Statistical differences were observed in MDA levels between I/R group with all groups (p<0.01), in addition there was difference between Tramadol with Sham, Per and Per+T groups (p<0.05), both in plasma and renal tissue.

Conclusion: Remote ischemic perconditioning was more effective reducing renal ischemia-reperfusion injury than administration of tramadol or association of both treatments.

■ Introduction

Acute renal failure (ARF) is a high incidence syndrome, responsible for a high rate of morbidity and mortality, affecting about 30% to 50% of patients in intensive care units. Among the characteristics of the ARF are decreased glomerular filtration rate, tubular necrosis, as well as abrupt increase in serum levels of urea and creatinine 48 hours.

The main cause is related to ischemia and reperfusion syndrome which is related to clinical situations the example of sepsis, shock, low cardiac output, or surgical procedures such as kidney transplants.

This syndrome is initiated from a local or general reduction of renal blood flow, which leads to depletion of intracellular ATP failure of ion pumps with ions entry osmotically active in the cell that result in cell swelling, the matrix and mitochondrial cristae. Furthermore, there is accumulation of substances such as xanthine oxidase, which plays a critical role in reperfusion injury.

Thus, in order to minimize the damage caused by oxidative stress on physiology of the body under ischemia/reperfusion, different therapeutic approaches were used, such as hypothermia, administration of antioxidant substances and hypertonic saline solutions.

There is also the technique of remote ischemic perconditioning, which is held remote ischemic conditioning by a tourniquet applied to the back of the animal member during the time of primary ischemia, which was used with excellence in prevent reperfusion injury in the myocardium. Its protective effect has also been demonstrated on the brain, renal and liver ischemia.

In addition, several studies in the literature have shown that opioid pathway is involved in preservation of tissues during hypoxia, which is mediated through μ-opioid receptor, among them is tramadol hydrochloride. Recent studies reveal the effect of this anesthetic in reducing lipid peroxidation. Furthermore, it was used for the management of myocardial ischemia and the brain tissue.

In view of the protective effects of ischemic conditioning described in the literature and its potential as a therapeutic approach to ischemia/reperfusion, this study aimed to evaluate the effects of tramadol, associated to remote ischemic perconditioning on oxidative stress in renal ischemia/reperfusion.

■ Methods

All experiments were performed in accordance with Brazilian law for scientific use of animals, and this project was formally approved by the local ethics committee for animal experimentation (Protocol 08/2015).

Twenty-five adult male Wistar rats aged 10-12 weeks (250-350g), were obtained from the Evandro Chagas Institute. The rats were maintained with free access to regular food and water, at 22±1°C under a 12-h light/dark cycle.

The animals were randomly distributed into five experimental groups, each with five rats: sham group (S) were submitted to all operative procedures, except vessels occlusion. I/R group were undergoing 30-minutes of ischemia and 24 hours of reperfusion. Remote ischemic perconditioning group (Per) were submitted to three cycles of 10-minutes of I/R with a tourniquet on left hind limb. Tramadol group were received subcutaneous administration of 40 mg/kg tramadol hydrochloride after ischemic period. Remote ischemic perconditioning + Tramadol group (Per+T) received both treatments (Figure 1).
The rats were fasted overnight before the experiments, but were given free access to water. They were weighed and anesthetized using an intraperitoneal injection of ketamine hydrochloride 10% and xylazine hydrochloride 2% (70mg/kg and 10mg/kg, respectively). During the operations, additional doses were administered if necessary.

**Experimental protocol**

All operations were performed under sterile conditions under constant temperature of 37°C. An abdominal incision was made; then the left renal artery and vein were occluded with a microvascular clamp for 30-minutes; after this process, the clamp was removed and the organ was allowed to reperfusion for 24 hours. Sham operations were performed in a similar fashion, except the vessels were not clamped. Surgical site was closed with 4-0 nylon.

**Samples collection**

The rats were euthanized by overdose of ketamine hydrochloride and xylazine hydrochloride injection (triple dose of anesthetic) at the end of the reperfusion period. The left kidney was harvested, and its adhering fatty tissue was carefully dissected. Then, 5ml of blood was also collected from inferior vena cava to assess oxidative stress.

**Preparation of kidney tissue homogenates**

The samples were washed three times in cold normal saline solution (0.9%). Then, the tissues were homogenized in ice-cold Tris-HCl buffer solution within a homogenizer for 2min at 11.200xg. The homogenate was centrifuged at 3500xg (4°C) for 60min, and supernatant was obtained. Malondialdehyde (MDA) levels were studied in the homogenate and for a further extraction procedure, the supernatant was extracted in ethanol/chloroform mixture (5/3 v/v). After a second centrifugation at 3500xg for 20min.

**Biochemical analysis**

The MDA levels in kidney tissues and plasma were analyzed by a method based on the reaction with thiobarbituric acid at 95°C. In the thiobarbituric acid test reaction, MDA or MDA-like substances and thiobarbituric acid react together to produce a pink pigment with an absorption maximum of 532 nm. The results were expressed as nmol/g.

**Statistical analysis**

All data was statistically analyzed using BioEstat version 5.4. Data were expressed as mean ± standard deviation. Analysis of variance (ANOVA) was used for statistical analysis of data among all groups. A value of p<0.05 was considered statistically significant.

**Results**

All rats survived without major complications. The values of MDA of each group are shown in Table 1.

Regarding plasma MDA levels (Figure 2), statistically significant difference of I/R was observed with the other groups (p <0.01) and Tramadol with Sham, Per and Per+T groups (p <0.05).

Discussion

This research demonstrated that remote ischemic perconditioning was more effective in reducing renal I/R injury than administration of tramadol or association of both treatments.

In this study, I/R group showed significantly higher MDA levels in both serum and tissue analyses as compared to Sham group, demonstrating that experimental model was efficient, promoting lipid peroxidation and oxidative stress.

MDA levels were significantly higher in I/R group as compared to perconditioning, tramadol and Per+T, suggesting that they were efficient to maintain a higher antioxidant defense which allows further destruction of oxygen free radicals, reducing lipid peroxidation mediated by these reactive species released from the kidney tissue.16

In kidney tissue, MDA showed a similar behavior when compared to plasma, a significant difference of I/R with the other groups (p<0.01) and Tramadol with the Sham, Per and Per + T groups (p<0.05) was also observed.

In kidney tissue, MDA showed a similar behavior when compared to plasma, a significant difference of I/R with the other groups (p<0.01) and Tramadol with the Sham, Per and Per + T groups (p<0.05) was also observed.

role on protective activity of ischemic perconditioning and tramadol. The mechanisms underlying the protective effects shown by ischemic conditioning remain unknown in the literature. However, it is suggested that initial mechanism of this process is the activation of neurohumoral pathway that activates defenses against the reperfusion injury of organs submitted to ischemia.

Thus, application of ischemic conditioning in a remote organ can induce the release of humoral factors - such as adenosine, bradykinin and opioids - that under local innervation, cause activation of neural pathways that leads to renal protection. These effector signals activates specific cellular events, such as signaling cascades, known as RISK (Reperfusion Injury Salvage Kinase) and SAFE (Survivor Activating Factor Enhancement) that promote cell survival and increase tissue antioxidant defense at the organ submitted to ischemia.

Furthermore, these results suggest that administration of tramadol, a centrally acting analgesic agent, may induce a renal protective effect against I/R oxidative injury. Many reports on literature describe beneficial use of this substance on experimental models such as transient forebrain ischemia, myocardial and skeletal muscle I/R. Therefore, intraperitoneal injection decreased cerebral I/R injury in a rat model. Further studies are necessary to evaluate the effects of tramadol on the renal function and histopathological aspects. Thus, alternative dosages and different protocols, such as intravenous, intraperitoneal or intramuscular administration of Tramadol, can be used in future researches.

■ Conclusions

Remote ischemic perconditioning was more effective reducing renal ischemia-reperfusion injury than administration of tramadol or association of both treatments.
