Potential preventive effect of *Lactobacillus acidophilus* and *Lactobacillus plantarum* in patients with polyps or colorectal cancer

Nazi ZINATIZADEH¹, Farzad KHALILI², Parviz FALLAH³, Malihe FARID⁴,⁵, Maryam GERAVAND¹ and Somayeh YASLIANIFARD⁶,⁷

ABSTRACT – Background – Colorectal cancer is one of the major causes of death worldwide. Many studies have been done on the biology of its formation as well as its treatment in recent years. One of the factors involved in the formation or treatment of this malignancy can be attributed to the microbial flora in the intestine. Objective – This study investigates the potential preventive effect of *Lactobacillus acidophilus* and *Lactobacillus plantarum* in patients with polyps or colorectal cancer (CRC). Methods – A total of 77 samples were selected in the form of three groups including individuals suffering from CRC, polyps and healthy subjects. Genomic DNA of fecal specimens and standard strains were extracted and amplified employing primers targeting of the 16S rRNA gene for initial detection. Absolute Real Time PCR quantification was used to determine the copy of the bacterial expression per gram of feces. Results – No significant difference were observed between age and gender in the mentioned groups (*P*=0.06). The average copy number of *Lactobacillus acidophilus* shows significant difference between the healthy group and those with polyps (*P*<0.0001), the healthy group and those with colorectal cancer (*P*<0.0001), as well as those with polyps and the colorectal cancer patients (*P*<0.0001). Conclusion – These results may indicate that taking *Lactobacillus acidophilus* in people with a family history of CRC and people with polyps may be a way of preventing, treating or reducing the severity of CRC.

INTRODUCTION

Colorectal cancer (CRC) is one of the leading causes of mortality in the world, which has grown significantly in recent years, may cause to malignancy(1). The presence of polyps in the inner wall of the colon is a high-risk complication for the development of CRC(2). Adenoma is the most common and important type of colon polyps, and it is the basis for the creation of tumors in the colon. The prevalence of this disorder is directly related to aging, and in countries with high prevalence, such as United States, fifty to sixty five percent of the population over 65 years old have Adenoma(3-5). The incidence of CRC in Iran is lower than that of western countries. It is the fifth most common diagnostic cancer in Iranian men and women population respectively(6). Statistics show that the incidence of illness in our country has increased over the past 25 years(7). Recent studies in Iran have also shown that about 43 percent of patients with CRC are under the 50 years old(8). Effective factors in CRC include genetic and environmental factors. Environmental factors in this disease are more important than genetic factors. The environmental factors including inappropriate diets such as high fat, low fiber, and low carbohydrates(9,10). Direct statistical correlation between germs and cancer has been identified(11), for example, *Fusobacterium* and *Escherichia coli* are now recognized as a primary cause of peptic ulcers and gastric cancers(12,13). Intestinal microbiota in human consists of two major phyla of Bacteroides and Firmicutes(14). In the intestinal flora there are two kinds of beneficial and harmful types of bacteria. Intestinal microbiota has different roles, including intestinal health, immune system modification, presence of drug metabolism, decomposition of carcinogenic factors, vitamin production, fermentation, electrolyte absorption, and epithelial cell growth, preventing the accumulation of pathogenic bacteria such as *Escherichia coli* and *Clostridium* in the intestines and preventing allergies(15). Probiotics are living organisms that, have an effect on the health of the host by affecting the microbial flora. Probiotics often belong to the human intestinal microbial flora. There is a belief in probiotics that the microbial flora of the intestine has a protective effect against disease. The protective role of probiotics is effective when treated as a microbial flora in the Intestine(16). The *Lactobacillus* family is one of the most important probiotics. This family consists of gram positive, catalase-negative and non-sporulated rods. Although there are many bacteria that have probiotic prop-
Zinatizadeh N, Khalili F, Fallah P, Farid M, Geravand M, Yaslianifard S. Potential preventive effect of Lactobacillus acidophilus and Lactobacillus plantarum in patients with polyps or colorectal cancer

This study, for the first time aimed to determine the mean population of Lactobacillus acidophilus and Lactobacillus plantarum in patients with polyps or CRC in comparison of healthy peoples to investigate the potential preventive effect of these bacteria on polyps or development of colorectal cancer.

METHODS

Sampling
Healthy peoples, individuals with polyps or CRC were diagnosed by a gastroenterologist using colonoscopy. CRC positive cases were confirmed by histopathology test. A total of 77 samples were selected in the form of three groups of 25 people including individuals suffering from CRC, 28 polyps and 24 healthy subjects, respectively. Exclusion criteria were a personal history of CRC, IBD or IBS and regular use of non-steroidal anti-inflammatory drugs (NSAIDS), statins, or probiotics. Patients did not receive antibiotics for one month before surgery. Fecal specimens were transported to the laboratory on ice and frozen at −80°C.

Preparation of standard strain
Standard strains of Lactobacillus acidophilus (DSM20079) and Lactobacillus plantarum (DSM20174) were prepared from the Iranian Biological Resource Center (IBRC). These strains were cultured in MRS agar and MRS broth media for 48 hours, then a suspension cultures of bacteria was prepared for isolation of genomic DNA.

Genomic DNA extraction
Genomic DNA of fecal specimens and standard strains were extracted using Qia amp DNA stool mini kit (Qiagen) and the tissue genomic DNA extraction mini kit (Favorgen Biotech Corp). According to the manufacturer’s instructions, respectively. Integrity size of DNA were checked by 0.1% agarose gel electrophoresis. DNA concentrations were determined with the Nano Drop 2000 (Thermo Scientific) and stored at −20°C prior to amplification steps.

Polymerase chain reaction (PCR)
Extracted DNA was amplified employing primers targeting of the 16S rRNA gene. Forward and reverse primers for Lactobacillus acidophilus and Lactobacillus plantarum were 5'-AATTCTCTTCTCGTCGCTCTA-3'; 5'-CCTTTCTAA-GGAAGCGAAAGAT-3', and 5'-TTACCTAACAGGTAATGCG- GA-3'; 5'-GCCGCTAAGTGGGACAGAT-3' respectively. The specificity of the primers was confirmed by PCR in 25 µL reaction mixtures containing 2.5 µL reaction buffer, 2 µL of template, 1 µL (each) primer, 1 µL DNTP (mix), 0.5 µL Taq polymerase, 2 µL DNA- template, 1 µL Mgcl2. PCR was performed with an initial denaturation step of 94°C for 5 min, followed by 30 cycles of 94°C for 1min, and 55°C for 30s.

10 µL of the PCR was subjected to electrophoresis on a 2% agarose gel containing Gelred, and the DNA bands were visualized by UV illumination to confirm the generation of 176-bp (Lactobacillus acidophilus), 166-bp (Lactobacillus plantarum) amplicons.

Real-time quantification PCR of total Lactobacillus acidophilus and Lactobacillus plantarum load
Quantitative RT-PCRs were performed in a reaction volume of 20 µL containing 10 µL SYBR Green PCR Master Mix, 1 µL each of the forward and reverse primers, 2 µL rox and 2 µL of DNA extracted from the fecal samples. The amount of DNA in the 77 fecal samples was determined in duplicate, and the mean values were calculated. Amplification and detection of DNA were performed with the LightCycler® system - Roche Life Science. The reaction conditions were 95°C for 2 min and 95°C for 5s, followed by 40 cycles of 95°C for 15 s and 55°C for 10s. Data analysis was conducted with sequence detection software lightcycler 96. Purified genomic DNA in the range 1 ng of Lactobacillus acidophilus and Lactobacillus plantarum were used as the standard for determining the amount of Lactobacillus acidophilus and Lactobacillus plantarum DNA by real-time PCR (FIGURE 1).

Absolute quantification was used to determine the copy of the bacterial expression per gram of feces using LightCycler® 96. In the sample editor section, at least three concentrations were

selected from the standard strains, and the copy number of the bacteria per gram of feces were determined in each sample based on the standard curves.

**Statistical analysis**

Descriptive data were analyzed with the Statistical Package for the Social Sciences 21 (SPSS 21). Chi-square, Mann-Whitney Test and Kruskal-Wallis Test were applied for data analysis. P values of <0.05 were considered significant.

**RESULTS**

**Sampling and demographic analysis**

Using ANOVA statistical test no significant difference was found between the ages of the studied groups (P>0.06). In addition no significant difference were observed between gender in the mentioned groups (P=0.06). The age range of 55-65 years included the highest number of polyps and CRC. In addition the results of statistical analysis showed that the frequency of O blood group is higher in patients with polyps and CRC (P<0.05). There were no significant differences in the other variables (TABLE 1).

**Specimens and DNA isolation**

To better demonstrate the distribution of bacterial DNA in samples taken from healthy peoples and those with polyps or CRC, the percentage of those carrying bacterial DNA was measured. All samples of healthy people and those with polyps contained DNA of *Lactobacillus acidophilus*. However, 86% of the subjects with CRC had DNA of *Lactobacillus acidophilus*. 100% of samples had *Lactobacillus plantarum* DNA.

**Real-time quantification PCR of total Lactobacillus acidophilus and Lactobacillus plantarum load**

The average copy number of *Lactobacillus acidophilus* was calculated in three groups studied (P<0.0001). A statistically significant difference was found between the healthy group and those with polyps, the healthy group and those with colorectal cancer, as well as those with polyps and the colorectal cancer patients (TABLE 2).

Average copy number of *Lactobacillus plantarum* was calculated in three groups and there was no significant difference between the three groups (P>0.05) (TABLE 3).

**DISCUSSION**

The number of bacteria estimated by the molecular techniques is greater than the total bacterial load detected by culture methods, demonstrating the utility of real-time PCR in the analysis of the bacterial load(29).

So far, no study has been done to determine the population of *Lactobacillus acidophilus* and *Lactobacillus plantarum* in patients with CRC and polyps. Therefore, the present study was conducted to determine the copy number of *Lactobacillus acidophilus* and *Lactobacillus plantarum* from fecal specimens of patients with polyps and CRC in comparison with control group. In this study, for the first time, Cyber Green method was used to check the copy of these two bacteria per gram of feces. According to the results of this study, The mean copy number of *Lactobacillus acidophilus* decreased in people with CRC compared to healthy subjects and people with polyps. Also, The mean of copy number of this bacterium is lower in people with polyps in comparison of healthy people.

Significant difference in the mean copy number of *Lactobacillus plantarum* in three groups was not observed. There are a variety of reasons, for example *Lactobacillus acidophilus* is one of the most important and most frequent colon flora and it may change faster than the changes in bowel conditions affected by polyps and CRC.

Studies indicate that the population of intestinal bacteria is different between healthy subjects and people with CRC(20). For example, researches have shown that in patients with CRC, the population of some bacteria such as *Escherichia*, *Citrobacter*, *Shigella* *Flavobacterium*, *Acinetobacter* and *Chryseobacterium* decreased(31).

Intestinal bacteria play different roles in inducing disease or protecting individuals. Some species exacerbate the formation of a tumor and cause cancer, while others contribute to the health of the intestine. For example, *Eubacterium rectale* and *Eubacterium eligens* are firmicutes, which have a significant correlation with CRC. While the intestinal proteobacteria population declines in patients with CRC(22).

Although most cases of CRC occur individually, the role of inherited genetic factors in the development of CRC is 35%. The first-degree relatives of CRC patients are at increased risk of CRC(23).

For example, in a family with two or more people with colorectal cancer, the relative risk for the other family members increases to 4.

Arq Gastroenterol • 2018. v. 55 n° 4 out/dez • 409
addition the relative risk of developing adenoma or CRC in people with a history of adenoma in their family increases to 2 folds\(^\text{25}\).

There is evidence that treatment with probiotics may modulate gastrointestinal function and reduce digestive disorders\(^\text{26}\). Ferment-ed products such as short chain fatty acids (SCFA) are produced by the consumption of probiotics\(^\text{27}\). Probiotics in the mouse colon have been shown to induce a protective glutathione transferases II enzyme. These factors reduce the burden of the genotoxic substances in the intestine and also increases the production of factors that disable toxic compounds, for example Butyrate is one of these protective factors that slows the propagation of cancer cells\(^\text{28}\). It was also observed that abundance of Bacteroides and Bifidobacteria was associated with a reduction in the risk of colon polyps\(^\text{29}\).

Considering the results obtained in this study as well as using the results of previous studies, it can be concluded that after the diagnosis of adenomatous polyps, doctors can prescribe probiotics to treat or prevent CRC. Older people can probably prevent the development of polyps or their progression to malignancy by including probiotics in their diet.

In this study, there is a significant difference in blood groups, so that in the blood group O, the number of people with polyps and CRC is more than other groups. It can be argued that colon cancer is more likely to occur in those who have a blood type O and they can prevent the disease by using a proper diet and taking probiotics. Periodic screening can be helpful to assess, diagnose and treat the disease at the early stages. Significant difference between smoking and CRC was not observed.

CONCLUSION

CRC is one of the leading causes of mortality in the world, which has grown significantly in recent years, and may cause to malignancy. In this study, there was a significant difference in population of \textit{Lactobacillus acidophilus} bacteria in patients with polyps, CRC and healthy subjects. However, no significant difference was found in the three groups in the study of \textit{Lactobacillus plantarum} population. These results may indicate the Potential preventive effect of \textit{Lactobacillus acidophilus} in people with a family history of CRC. In addition, this bacterium may be used as a supplement to patients with intestinal polyps in the future. Further studies are needed to confirm the preventive or therapeutic role of this bacterium.

ACKNOWLEDGEMENT

We thank the Staff of Bahonar Hospital in Alborz Province for providing the fecal samples that were used in this study.

RESUMO – Contexto – O câncer colorretal é uma das principais causas de morte em todo o mundo. Muitos estudos têm sido feitos sobre a biologia de sua formação, bem como o seu tratamento nos últimos anos. Um dos fatores envolvidos na formação ou no tratamento desta malignidade pode ser atribuído à flora microbiana no intestino. Objetivo – Este estudo investigou o potencial efeito preventivo de \textit{Lactobacillus acidophilus} e \textit{Lactobacillus plantarum} em pacientes com pólipos ou câncer colorretal (CCR). Métodos – Um total de 77 amostras foram selecionadas e três grupos foram formados, a saber, indivíduos portadores de CCR, pólipos e indivíduos saudáveis. O DNA genômico de espécimes fecais e de amostras padrão foi extraído e amplificado empregando primers que focalizaram o gene do rRNA 16S para a detecção inicial. A quantificação do PCR em tempo real absoluto foi utilizada para determinar a cópia da expressão bacteriana por grama de fezes. Resultados – Não foram observadas diferenças significativas entre idade e sexo nos grupos citados (\(P>0,06\)). O número médio de cópias de Lactobacillus acidophilus mostra diferença significativa entre o grupo saudável e aqueles com pólipos (\(P<0,0001\)), o grupo saudável e aqueles com câncer colorretal (\(P<0,0001\)), bem como aqueles com pólipos e câncer colorretal pacientes (\(P<0,0001\)). Conclusão – Estes resultados podem indicar que a ingestão de Lactobacillus acidophilus em pessoas com antecedentes familiares de CCR e pessoas com pólipos pode ser uma forma de prevenir, tratar ou reduzir a gravidade da CCR.

DESCRITORES – Neoplasias colorretais. Pólipos. Probióticos. \textit{Lactobacillus acidophilus}. \textit{Lactobacillus plantarum}.
