ESTHESIONEUROBLASTOMA

Case report

Jackson Gondim¹, Francisco Ramos Jr², Jorge Azevedo³, Fernando Porto Carrero Jr³, Oswaldo Inácio Tella Jr⁴

ABSTRACT - Esthesioneuroblastoma (ENB) is a rare tumor arising from the olfactory epithelium of the nasal vault which frequently invades the cranial base, cranial vault and orbit. ENB has a bimodal age distribution between 11 and 20 years and between 51 and 60 years. ENB accounts for approximately 1 to 5% of intranasal cancers and no consensus has been reached regarding treatment of this tumor. We report on a 66 year old female patient with a Kadish stage C tumor with frontal lobe invasion submitted a total craniofacial resection with a combined head neck and neurosurgeon team. The purpose of this study is to analyze the natural history, treatment and prognosis of this tumor, based on the literature review.

KEY WORDS: esthesioneuroblastoma, craniofacial surgery, skull base surgery.

Esthesioneuroblastoma: relato de caso

RESUMO - Esthesioneuroblastoma é um tumor raro originado do epitélio olfativo, frequentemente invadindo a base do crânio e a região orbitaria. É tumor que pode ser encontrado em qualquer idade mas apresentando dois picos de frequência entre 11 e 21 anos e 51 e 60 anos, raros em criança. A distribuição por sexo é praticamente igual mas com uma pequena predominância masculina. O diagnóstico histopatológico é feito de forma definitiva por métodos imunohistoquímicos. A sintomatologia clínica corresponde ao de uma neoplasia intranasal ou frontobasal. Devido a raridade destes tumores não se chegou ainda a um consenso em relação ao tipo de tratamento. Relatamos o caso de uma paciente 66 anos de idade com um tumor classificado como Kadish tipo C, com invasão dos seios da face e lobo frontal, que foi submetida a ressecção crânio facial por uma equipe multidisciplinar. A história natural o tratamento e o prognóstico dos pacientes portadores destes tumores serão analisados baseando-se numa revisão da literatura.

PALAVRAS-CHAVE: esthesioneuroblastoma, cirurgia crânio facial, cirurgia da base do crânio.

Esthesioneuroblastoma (olfactory neuroblastoma) (ENB) is a rare neuroepithelial tumor that arises from the olfactory epithelium in the cribriform place or nasal cavity¹. First described in 1924 by Berger² it has a histological pattern similar to that of sympathetic ganglia, retina, and adrenal medulla² and only recently³ became recognized as a distinct pathologic entity probably as a result of immunohistochemistry and by means of electron microscopy techniques. They have helped differentiate ENB from similar undifferentiated nasal cavity tumors⁵. ENB account for 1 to 5% of malignant neoplasms of the nasal cavity. Fewer than 945 cases are reported in the world literature⁴, and most of the reports were in small series. Unlike most other neuroectodermal tumors, which manifest in childhood, ENB, has a bimodal age distribution between 11-20 years and 51-60 years⁵. The symptoms are related to sites and invasion of the tumor. The staging system based on tumor extension that was presented by Kadish et al.⁶ in 1976 has been widely accepted. The treatment of choice is a multidisciplinary craniofacial surgical resection that has improved considerably the prognosis.

The purpose of this study is to analyze the natural history, treatment and prognosis of this tumor, based on the literature review.

CASE

A 66 years old woman with a one year history of constant bifrontal facial headache, nasal obstruction, anosmia

has presenting for about two months visual blurring, lacrimation and ocular pain followed one week later by epistaxis. Physical examination revealed a bilateral nasal mass that was endonasal endoscopy biopsy-proven to be an ENB. CT and MRI (Fig 1) demonstrated that the tumor filled the entire nasal cavity, ethmoid sinuses, sphenoid sinus, and left frontal sinus. The tumor invaded the cribiform plate and the left frontal lobe. The patient underwent a craniofacial resection with a combined neurosurgeon and head neck surgeon team. A bicoronal incision with frontal craniotomy, and in bloc resection of the frontal tumor and frontal base with preservation the pericranial flap, that was placed along the floor of the anterior cranial fossa and sutured to the residual sphenoid bone as well as though the residual dura, combined with an extended lateral rhinotomy, with totally resection of the infra cranial tumor. In the post operatively MRI (Fig 2), no tumor was found. The patient receives 56 Gy of external beam radiotherapy over a 6-week period, and chemotherapy. She showed no recurrence after one year.

Fig 1. Preoperative sagittal MRI of the tumor, involving the ethmoid sinus, sphenoid sinus, nasal cavity and frontal lobe.

Fig 2. Postoperative one month sagittal MRI, with no more tumor.
DISCUSSION

Esthesioneuroblastoma is a very rare malignancy of the neuroepithelium. It was first described by Berger et al. in 1924, as “l’esthesioneuroepitheliome olfactif” and was only introduced into the American literature by Schall and Lineback in 1951. Nearly all of the 945 cases have been reported within the last 40 years. Embryologically, the olfactory nerves develop from the olfactory placode present in the fetal olfactory mucosa. Histologically, there are a number of criteria that help in its diagnosis: neuroepithelial cells arranged in the classic pseudorosette pattern; fibrillar intracellular background; marked microvascularity; and round or fusiform cells approaching the size of lymphocytes with poorly defined, almost nonexistent cytoplasm. Correct diagnosis often requires confirmatory examination with electron microscopy for the detection of neurosecretory granules. More recently immunohistochemical methods for detection of neuronspecific enolase (NSE) and S-100 protein with negative epithelial, muscle, and lymphoid antigens allowed further confirmation of ENB. This tumor must be differentiated from neoplasm of the nasal cavity and paranasal mucous, such as lymphoma, sarcoma, plasmacytoma, malignant melanoma, anaplastic carcinoma, rhabdomyosarcoma, and transitional cell carcinoma.

ENB has a bimodal age distribution with an early peak from 11 to 20 years and a later peak between 51 and 60 years of age. Our patient was a 66 years old woman. There is a slight male predominance. The staging system based on tumor extension that was presented by Kadish et al. in 1976 has been widely accepted. This staging system is predictive of disease-related mortality. The system classifies patients with tumors limited to the nasal cavity as stage A. Patients with tumors involving the nasal cavity and extending into the paranasal sinuses are stage B, and stage C are tumors spreading beyond the nasal cavity and paranasal sinuses, as our patient. This system has been advocated by some, because of its simplicity and acceptable prognostic efficacy. Recently, Morita et al. justified a modified classification with stage D tumors, presenting metastases in cervical lymph nodes distant. Two other staging methods, the Biller method and the Dulguerov method, have also been described and used.

ENB is a slow growing tumor and the patients may have a history of progressive symptomatology for months to years, our patient has a one-year evolution. The presenting symptoms are nonspecific and related to the sites and invasion of the tumor. The most common finding on physical examination was the presence of a nasal mass as our patient. Recurrent epistaxis is sometimes present. Penetration into the cribriform plate can cause anosmia. Ophthalmological symptoms as ptosis, diplopia, visual blurring, ocular pain, proptosis, and excessive lacrimation may be found. Ear pain and otitis can result from tumor obstructing the Eustachian tube. Frontal headache suggests involvement of the frontal sinus. Cranial nerves may also be affected inducing nerve paralysis. Alteration of mental status may be present if frontal lobe is invaded.

The diagnosis and evaluation of staging of ENB can be done by CT, which provides the best information about the tumor invasion into bony structures. The tumor is presented as a homogeneous density mass, equal to or greater than the surrounding soft tissues. There are no tumor cysts or calcifications. Contrast enhancement was usually moderate and homogeneous. Coronal images were of value in evaluating extension to the orbital and through the cribriform plate and the anterior cranial fossa. MRI shows a tumor hypointense to gray matter on T1-weighted images and iso or hypointense on T2-weighted images. Gadolinium enhancement was observed to some degree in all cases. Fat saturated T2-weighted spin-echo images with and without gadolinium enhancement of particular value in differentiating enhancing tumor from post-obstructive mucous debris and evaluating tumor extension to the non-enhancing orbital fat. MRI is more accurate in depicting the exact margins of intracranial tumor extension because of its multiplanar display and superior tissue contrast.

Metastasis occurs in about 10 to 30% of patients. The most common sites for metastasis spread are the cervical lymph nodes, less frequent are lung and pleura, brain, bone, spinal column, breast, and abdominal viscera. Metastasis to the central nervous system is infrequent and usually identified only at post-mortem examination. In the spinal cord 80% of metastasis are in the cauda equine.

Our patient underwent a combined craniofacial approach utilizing a bicoronal flap for superior exposure and a lateral rhinotomy for infracranial exposure. Reconstruction varied according to the extent of the surgical resection and resultant defect. We do not use bony reconstruction of the floor of the anterior cranial fossa and supraorbital areas, but the pericranial flap is placed along the floor of the anterior cranial fossa and sutured to the residual sphenoid bone and residual dura matter to obtaining a...
watteright dural seal. Fibrin glue is use to assist du-
ral seal and to secure a watteright closure. There are
great variations in treatment for ENB. Some series
advocate a protocol with surgery\textsuperscript{15,18-22}, radiotherapy\textsuperscript{1,10,19,23}, alone, combined surgery and pre op-
erative radiotherapy\textsuperscript{23,24}, and combined surgery and post-
terative radiotherapy\textsuperscript{22,25}. The optimum manage-
ment for ENB is probably surgery using the concept
first described in 1971 by Doyle and Payton\textsuperscript{26}: rad-
cal surgery with a combined craniofacial approach\textsuperscript{12}
taken by craniofacial team, including neurosurgery
and head neck surgery. This technique has provided
enhanced exposure and the possibility to achieve
gross total resection. In patients without extension
of tumors to the superior nasal vault or the cribiform
plate, an intracranial exploration and remove of the
floor of the anterior cranial fossa must be performed.
This approach has had a decrease incidence of local recurrence\textsuperscript{1}. It is proved that the bone in this area
may harbor tumor cells with a potential cause of recu-
currence. This was done with our patient that had an
involvement of cribiform plate and frontal lobe.
We also used an adjuvant postoperative radiotherapy
with 50-60 Gy resulted in effective local control as
indicated by other authors\textsuperscript{10,27}. Furthermore the ra-
diotherapy is recommend for palliative treatment\textsuperscript{27}.
The role of systemic chemotherapy in the treatment
of ENB has range from no response\textsuperscript{18,32}, palliation\textsuperscript{20,33},
partial\textsuperscript{14,33-37} and complete response\textsuperscript{36,38,39}. In general
chemotherapy is usually reserved for tumor spread-
ning beyond the nasal cavity and paranasal sinuses\textsuperscript{12},
or in the treatment of distant metastases\textsuperscript{40}.

Treatment complications with ENB are high. Vi-
ual impairment is the most common adverse ef-
fct\textsuperscript{13}, because the location of the tumor is difficult
to deliver an adequate dose of radiation without ex-
ceeding the tolerance of critical structures such as
the brain, optic chiasm and orbits.

The prognostic factors in the management of ENB
are very controversy because of the small number of
patients presented in each series. Morita\textsuperscript{1} and Foo-
ter\textsuperscript{41} advocated that the only reliable survival predictor is
the tumor’s pathological grade (Hyams’ grading sys-
tem\textsuperscript{22}). Polin\textsuperscript{31} was unable to find significant dif-
ference between survival of patients with low and high-
grade tumors. Some authors\textsuperscript{16,43} affirm that the nega-
tive prognostic include age, metastasis, recurrence,
and extensions to the ethmoidal, nasopharyngeal and
orbital area. They also noted that the absence of me-
tastasis does not necessarily confer a good progno-
sis. Goldsweig\textsuperscript{34} concluded that the degree of resec-
tability of the tumor on primary surgery is the best
predictor of long-term survival. Irish determined a
100% 2-year survival rates in patients undergoing
combined surgical and radiation treatment. Polin\textsuperscript{31}
informs the 5 and 10 years survival rates of 87 and
54% respectively and a 97% one year survival. Pa-
tients with stage C disease have 96% one-year sur-
vival, 71% five years and 44% 10 years survival\textsuperscript{21}. In
the series of Jekunen\textsuperscript{40} the median survival time for
11 patients was 27 months, and the median disease-
free was 27 months. In the literature the 5-year re-
currence free survival is report to be between 52% and
90\%\textsuperscript{16,29,40}.

ENB recurs locally in up to 60% of patients who
undergo surgery\textsuperscript{15}, and its locally aggressive behav-
or is the most common cause of death\textsuperscript{44}. Median
survival after recurrences was only 12 months\textsuperscript{45,46}.
The majority of recurrences occur within the first
few years after treatment.

In conclusion, ENB is a very uncommon malignant
tumor arising from olfactory epithelium, that have a
long natural history characterized by frequent
local or regional recurrence. Radical craniofacial re-
sections by a multidisciplinary surgical team com-
bined with adjuvant radiotherapy with 50-60 Gy, is
probably the most usual treatment. The role of sys-
temic chemotherapy in the treatment of distant metastasis should be further evaluated.
