Abstract – On February 12, 2009, we commemorated the 200th anniversary of Charles Darwin's birth and the 150th anniversary of the publication of the first edition of the “On the origin of species”. Only in the sixth edition of the Origin Darwin explicitly stated that natural selection applied to the brain as to all other organs and contemporary epilepsy research plays an interesting role in this scenario. Epilepsy affects approximately 3% of the general population and is a complex disease. At least 11 genes have now been described for human epilepsy and over 50 more genes have been identified in animal models of epilepsy. The complex gene to gene interactions and gene-environment interactions may account for epilepsy susceptibility and antiepileptic drug response. Darwin’s thoughts on evolution are relevant to understand these gene interactions, contributing to current development of new treatments and prevention of chronic diseases, such as epilepsy.

KEY WORDS: Darwin, epilepsy, gene.

as I believe, is that the modified offspring of all dominant and increasing forms tend to become adapted to many and highly diversified places in the economy of nature.” With these observations, he proposed a theory of evolution occurring by the process of natural selection. The animals and plants best suited to their environment are more likely to survive and reproduce, passing on the characteristics which helped them survive to their offspring. Gradually, the species changes over time. Darwin worked on his theory for 20 years and, in 1859, he published “On the origin of species”⁴. Therefore, Darwin expressed his theory eloquently in 1859:\textsuperscript{5} “As many more individuals of each species are born than can possibly survive; and as, consequently, there is a frequently recurring struggle for existence, it follows that any being, if it vary however slightly in any manner profitable to itself, under the complex and sometimes varying conditions of life, will have a better chance of surviving, and thus be naturally selected. From the strong principle of inheritance, any selected variety will tend to propagate its new and modified form.” So in the current year we also celebrate the 150\textsuperscript{th} anniversary of the publication of the first edition of the \textit{Origin}\textsuperscript{3}.

Quite interestingly, Darwin had very little to say about the brain in the first edition of the \textit{Origin}\textsuperscript{3}. A search through the digitized version of his work (http://darwin-online.org.uk) brings up only one mention of the word ‘brain’, and that is in the context of describing the skull and the axial skeleton\textsuperscript{1,4}. The increased focus on the brain appeared only in the sixth edition of the \textit{Origin}, which contains a passage explicitly stating that natural selection applies to the brain as it does to all the other organs\textsuperscript{5,6}. Actually, 150 years after Darwin published the first edition of the \textit{Origin}, we have learned much about how his theory of evolution via natural selection is relevant to contemporary medicine\textsuperscript{7}. Furthermore, there are several relevant evolutionary explanations for diseases nowadays, but one of the commonest evolutionary explanations for the origin of human diseases focuses on mismatches between genes and the environment\textsuperscript{6}. Along these lines, the contemporary epilepsy research also plays an interesting role in this scenario. Epilepsy is one of the commonest neurologic problems worldwide\textsuperscript{8}. Approximately 2 million people in the United States have epilepsy, and 3 percent of the general population will have epilepsy at some point in their lives\textsuperscript{6}. Furthermore, it has to be acknowledged that more than 80\% of people with epilepsy live in developing countries, where the condition remains largely untreated\textsuperscript{8}. These people could lead normal lives if properly treated, but the majority of them do not receive any effective treatment\textsuperscript{7,9,10}. Because epilepsy is a complex disease, genetic influences as causal factors of the epilepsies can point the way to new treatment strategies. On the basis of these facts, an elegant study recently reviewed the progress in this area and suggested specific goals that once accomplished promise to lead to cures for epilepsy\textsuperscript{7}. Thus, at least 11 genes have now been described for human epilepsy and over 50 more genes have been identified in animal models of epilepsy\textsuperscript{11-13}. Alternatively, the specialists believe that the progress in understanding epilepsies of complex genetic origin will require not only identification of individual susceptibility alleles and analysis of gene to gene interactions, but also the study of gene-environment interactions\textsuperscript{11}. Clinical and experimental evidence supports these considerations. To begin with, it has been demonstrated that family members of individuals with acquired epilepsy are at higher risk of seizures compared with the general population\textsuperscript{11,14,15}. This topic is supported by a recent study demonstrating that the HLA-B*1502 gene could contribute to the pathogenesis of Stevens-Johnson syndrome and toxic epidermal necrolysis in Asian patients, and that genetic susceptibility to carbamazepine-induced cutaneous adverse drug reactions is phenotype-specific\textsuperscript{16}. In these circumstances, pharmacogenetic approaches to epilepsy
are already beginning to produce clinically important resolutions in the treatment of patients with epilepsy. For instance, the US Food and Drug Administration (FDA) has recently expanded an alert on the commonly used carbamazepine where a newly developed genetic test for risk of severe skin reactions is recommended\(^\text{11}\).

On the whole, despite repeated bouts of illness during the last twenty-two years of his life, Darwin still worked on his contributions to the evolutionary theory almost until his death on April 19, 1882. To date, it is clear that Darwin’s thoughts on evolution have influenced many science disciplines. An understanding of gene-environment interactions and its relevance to the current treatment or prevention of chronic diseases, such as epilepsy, is the key to what Dr. Charles Darwin called evolutionary science.
