ABSTRACT

The biooxidation of limonene by an Aspergillus strain resulted in the production of perillyl alcohol and short chain fatty acids. Addition of ketoconazole, a known inhibitor of cytochrome P450 oxidase, eliminated the production of free acids, but did not affect biotransformation to perillyl alcohol.

Key words: Limonene, biotransformation, perillyl alcohol, cytochrome oxidase, inhibitors

INTRODUCTION

D-limonene (4-isopropenyl-1-methylcyclohexene) is one of the most widely distributed monoterpenes and is biosynthesised by more than 300 different plants (Burdock, 1995). (4 R) - (+) - limonene (Fig. 1, 1) is the most frequent isomer, being the main constituent of citric essential oils, where it represents between 70 and 96% (Braddock & Cadwallader, 1995; Bruneton, 1995; Evans, 1989). In uruguayan citric essential oils, it represents 70% of the lemon oils and 93% of the sweet orange oils (Dellacassa et al., 1991). Limonene does not contribute to the aroma, so it is usually separated from the oils by deterpenation processes. It is therefore abundant and low priced, and is frequently used as substrate for the chemical synthesis of nature-identical odorants (Braddock & Cadwallader, 1995; Evans, 1989; Nonino, 1997; van Dyk et al., 1998).

The biotransformation of (+)-limonene using different microorganisms (bacteria, yeasts and fungi) has been extensively studied, searching for ways of producing compounds of higher value. Different oxygenated terpenes have been reported as biosynthetic products (α-terpineol, perillyl aldehyde, carveol, carvone, piperitone, etc.) (Abraham et al., 1986; Bowen, 1975; Braddock & Cadwallader, 1995; Kraidman et al., 1969; Murdock & Allen, 1970; Mukherjee et al., 1973; Noma et al., 1992; Rama Devi & Bhattacharyya, 1977; Tan & Day, 1998; van Rensburg et al., 1997).

Using an Aspergillus niger strain isolated from sweet orange peels we observed the production of mixtures of free short-chain organic acids and perillyl alcohol (Fig. 1, 2). To study the possible enzymatic systems involved in these oxidations, we added ketoconazole, which is known to inhibit cytochrome P450 oxidase (Karp et al., 1990) to the growth media.

MATERIALS AND METHODS

Reagents

Analytical grade solvents (Merck, Darmstadt, Germany) were distilled prior to use. Pure d-limonene was from Fluka (Basel, Switzerland). Ketoconazole was from Roemmers (Montevideo, Uruguay). Pure standards were from Aldrich (Milwaukee, USA).

Gas chromatography

A Shimadzu GC14B gas chromatograph (Kyoto, Japan) equipped with FID and EZChrom integration software for data processing was used. Fused silica capillary columns (30 m x 0.32 mm i.d.) with bonded SE52 (0.40 – 0.45 µm thickness) and Carbowax 20M (0.25 µm thickness) were used. Temperature programme: 60°C, 8 minutes; 60°C – 210°C at 3°C/min; injector temperature: 240°C; detector temperature: 250°C. Carrier gas: H₂ at 0.50 kg/cm²; injection system: split, ratio 1:100.

GC-MS were completed with a Shimadzu QP 1100-EX in the same conditions, using He as carrier gas. The identifications were completed by comparison of retention times against standards and Kovats indexes, and by MS using a Wiley spectra library.

Microorganism and culture

An A. niger strain was isolated from sweet orange peels and kept at the Collection of the Cátedra de Microbiología (Facultad de Química, Montevideo, URUGUAY) as BFQU 68. The strain was grown in PDA slants (DIFCO, Detroit, USA) at 28°C until sporulation, and then kept at 4°C. Growth Media was TSB (Sigma, St. Louis, USA).

The innoculum was a spore suspension adequate for a final concentration of 10⁵ spores/mL in the growth media, prepared from a fresh culture of 72 hrs. growth.

The growth experiments were carried out at room temperature (28°C) in a Sanyo IOC400.XX2.C orbital shaker (Tokyo, Japan) at 100 r.p.m.

Trial runs

Experiments with inhibitor (Trial 1) and without inhibitor (Trial 2) were carried out in quintuplicate.

RESULTS AND DISCUSSION

Gas chromatography indicated the presence of 5 main components after comparison of the results from Trial 1 and blank experiments. The four biotransformation products are shown in Table 1.

Propanoic, isobutyric and isopentanoic acids (Dhavalikar & Bhattacharyya, 1966; Dhavalikar et al., 1966), perillyl alcohol (van der Werf et al., 1999) and 2,5-dimethylpyrazine (Fig. 1, 3) are present together with residual limonene (Fig. 2). When ketoconazole was added (Trial 2) the only biotransformation products present were perillyl alcohol and 2,5-dimethylpyrazine (3).

The production of 2,5-dimethylpyrazine cannot be explained by any simple biotransformation of the
structure of limonene, but it is clearly absent in both blanks (Fig. 4), so its formation seems to be directly related to the presence of the terpene.

![Structures of Compounds](image)

**Figure 1** - 1. d-limonene, 2. Perillyl alcohol, 3. 2,5-dimethylpirazine.

Ketoconazole is a inhibitor of cytochrome P450 oxydase (Karp et al.), and when present in the growth media clearly inhibits the synthesis of short chain free fatty acids (Figs. 2 and 3). There is no inhibition of the oxidation of limonene to perillyl alcohol, so this transformation seems to proceed through a different oxidation mechanism.

Conclusions
The biotransformation of d-limonene to the free short-chain fatty acids by *A. niger* and the inhibition of their biosynthesis by ketoconazole implies the participation of a form of cytochrome P450 oxydase in the reaction. This does not apply to perillyl alcohol. The use of a cytochrome P450 oxydase inhibitors in similar biotransformations could be a method of orienting the resulting reactions to specific products.

**ACKNOWLEDGEMENTS**

The authors are grateful to CSIC (Universidad de la República, Montevideo, URUGUAY; pre-
Industrial Project 190) and to PEDECIBA-Química (Montevideo, URUGUAY) for financial support which made this work possible; to Q.F. L. Ferrando and Bach. G.González for technical help.

RESUMO

A biooxidação do limoneno por uma linhagem de Aspergillus resulta na produção de álcool perilico e ácidos graxos de cadeia curta. A adição de quetoconazol, um conhecido inibidor da citocromo P450 oxidase, elimina a produção de ácidos graxos livres, mas não afeta a biotransformação a álcool perilício.
