Abstract

Campomanesia phaea (Myrtaceae), popularly known as cambuci, is one of several species of plants producing comestible fruits, largely used in human nutrition. Despite its consumption and economic potential, limited scientific research is available on the Campomanesia, especially those related to its therapeutic benefits. It is reported by traditional medicine the use of the plant in the treatment of different disorders, such as cardiovascular and nervous system disturbances. So, the aim of this study was to carry out the pharmacological evaluation of the hydro-alcoholic extract (HAE) of Campomanesia fruits in rats by screening consisting of tests: a) neuropharmacological observation, b) test on the cardiovascular system. The HAE, prepared from the extraction of fruits with water/ethanol, was concentrated and freeze-dried. Behavioral responses in rats were investigated in open field test and the cardiovascular actions were investigated by a register of indirect blood pressure and the register of spontaneous beating rate right atrium. The results revealed that HAE induced grooming, hypotension and bradycardia. So, this study identified an action on the central nervous system, represented by grooming, and a cardiovascular activity of Campomanesia. The hypotension, attributed in part to bradycardia, was not related to a cholinergic effect, discarding a possible cholinomimetic action of the plant that could justify both cardiovascular and central actions.

Keywords: Campomanesia phaea, hypotension, bradycardia, grooming, rats.

1. Introduction

Campomanesia phaea (Myrtaceae), popularly known as cambuci, is one of several species of plants producing comestible fruits, largely used in human nutrition in juices, jellies, ice-creams and alcoholic drinks (Maluf and Pisciottano-Ereio, 2005; Leão et al., 2017). It is found in Brazil, in an area called Atlantic Forest, mainly
in the states of São Paulo and Minas Gerais (Maluf and Pisciottano-Ereio, 2005) and it could be considered with high economic value and environmental impacts, which influences the local business chain and contributes to the sustainable development of local society (Leão et al., 2017).

Phytochemical studies of this specie indicated a large amount of oil essential rich in linalool, caryophyllene oxide, beta-caryophyllene, beta-selinene and alpha-cadinol, constituents that show enormous commercial value to the cosmetic industry (Vallilo et al., 2005; Adati and Ferro, 2006).

The *Campomanesia*’s fruits are astringent and have antioxidant properties attributed mainly to bioactive compounds as L-ascorbic acid and compound phenolic (Leão et al., 2017; Azevedo et al., 2017). In addition, phenolic compounds obtained from the fruits were also shown effective in ameliorating glucose tolerance, as well as reducing insulinemia and fasting glycemia, and improving dyslipidemia by increasing HDL-cholesterol and decreasing the LDL-cholesterol (Donado-Pestana et al., 2015). So, they may help in healthy diets in order to prevent health risks, as oxidative stress, cardiovascular disorders, degenerative diseases and inflammatory process (Leão et al., 2017).

Despite its consumption and economic potential, limited scientific research is available on the *Campomanesia*, especially those related to its therapeutic effects. It is reported by traditional medicine the use of the plant in the treatment of different disorders, such as cardiovascular and nervous system disturbances (Branco, 2018; IBI Garten, 2018), although no pharmacological study has been conducted to date to validate these information.

So, the aim of this study was to carry out the pharmacological evaluation of the hydro-alcoholic extract of *Campomanesia phaeo* fruits in rats by screening consisting of tests: a) neuropharmacological observation, b) test on the cardiovascular system.

### 2. Material and Methods

#### 2.1. Plant material

The fresh fruits of *Campomanesia phaeo* (O.Berg) Landrum (The Plant List, 2018) were purchased from a commercial source in Vila de Paranapiacaba/Santo André-SP and were kept at -80 °C until use. The material (270g) was triturated and extracted with 1L of distilled water/ethanol (50:50). The soluble fraction of the extraction was filtered, concentrated and freeze-dried yielding the hydro-alcoholic extract (HAE) with a 10% yield.

#### 2.2. Animals

A total of 40 three-month-old Wistar rats weighing from 220 to 300g were used in this study. Animals were housed in groups of five and maintained in a temperature controlled environment (22 ± 2 °C), 50% humidity level and 12h light-dark cycle (lights on at 06:00h). Rats had free access to food and water. All procedures were performed in strict accordance with the guidelines of the Colégio Brasileiro de Experimentação Animal (COBEA, Brazilian Committee on Animal Research Ethics) and the National Institute of Health Guide for the Care and Use of Laboratory Animals (NIH Publications 80-23). The experimental protocols were submitted for evaluation by the Comissão de Ética no Uso de Animais (CEUA) of the Santa Casa de Sao Paulo Medical School being approved (protocol 006/16).

#### 2.3. Bioassays

a) Neuropharmacological observation in rats: Investigation of the behavioral response in the open field

Open field test is a classic experimental model used to investigate exploratory activity and emotional behavior in rodents (Prut and Belzung, 2003; Gamberini et al., 2015b; Schatz et al., 2018). For this evaluation, rats fasted for 2 hours prior to the experiment were divided into four groups: group 1 (control) received water (5mL/Kg) whereas the others groups received 0.5, 1.0 and 2.0g/Kg of hydro-alcoholic extract (HAE), respectively. All groups received a single individual dose by gavage. Thirty minutes after administration, spontaneous activity was evaluated in an open field arena measuring 100cm in diameter with a wall 40cm in height. From the center, radii divided the floor into four concentric circles, forming 46 divisions (the innermost circle was not divided). The rats were placed at the same starting point and allowed to freely explore the apparatus for 5 minutes. The following measurements were then recorded for each individual rat to assess their behavior while in the open field: peripheral locomotor activity (number of grid crossings, defined as the movement of two limbs from one section to another in the two peripheral circles); central locomotor activity (number of grid crossings in the two innermost circles); number of rearings (forepaws raised with the head held up); and immobility (all limbs stationary on the floor). Grooming time and the number of defecations were also recorded. After each trial, the apparatus was wiped clean with a 5% ethanol solution. All observations for each rat were made at comparable times of day during the light period of the light/dark cycle.

b) Tests on the cardiovascular system in the rat

b.1) Indirect measurement of blood pressure in non-anesthetized animals

The systolic blood pressure (SBP) of the rats was measured using a non-invasive method (Alexander, 1957; Trindade et al., 2018; Aekthammarat et al., 2019). Initially, the animals were treated daily with distilled water (5mL/Kg, p.o.) and submitted, on alternate days, to measurement of SBP using the tail-cuff method. For the measurement, the animal was placed in a rat holder with its tail remaining free for the fitting of a pressure cuff coupled to a sphygmomanometer. Prior to taking pressure measurements, the non-anesthetized animal was left for a period of 5 minutes to adapt to the system in order to avoid pressure variations. After allowing
10 days for blood pressure stabilization, assessment of the effect subacute (7 days) administration of different doses (HAE 0.5, 1.0 and 2.0g/Kg, p.o.) were performed. A group treated with water (5mL/Kg, p.o.) was maintained throughout the assessment period and submitted to the same procedures for determining SBP. In all the groups, the blood pressure of the animals was assessed 1 hour after administration of the water or the HAE and the same procedure was repeated for 7 days.

b.2) Measurement of the spontaneous beating rate of the right atrium

The cardiac effects of *Campomanesia* were investigated from the actions of the HAE on the sinus node, the major cardiac pacemaker. For this, rat was anaesthetized with isoflurane inhalation and the heart was quickly removed. The right atrium was carefully dissected and mounted vertically in a 3mL double walled glass chamber filled with Tyrode solution with the following composition (in mM): NaCl 119.0; KCl 4.6; MgCl\(_2\) 1.2; NaHCO\(_3\) 15.0; CaCl\(_2\) 1.5; NaH\(_2\)PO\(_4\) 1.2; Glucose 11.0. The organ was gassed continuously with 95% O\(_2\)-5% CO\(_2\) and maintained at pH 7.4 and 36\(^\circ\) C. The lower end of the right atrium was fixed on a hook and the upper end was connected by a silk thread to an isometric force-displacement transducer (Grass FT-03). A preload tension of 1.0g was applied to the atria and the tissues were allowed to equilibrate for 1 hour before drug administration (Nasa et al., 1992; Merino et al., 2015). The spontaneous beating rates of the right atrium in the absence and the presence of HAE 10mg/mL were recorded on a polygraph (Gemini, Duo Chanel, Ugo Basile) and was expressed as beats min\(^{-1}\). For the investigation of the possible cholinomimetic effect of the HAE, some experiments were made using a non-selective antagonist cholinergic receptor, atropine 1mM, incubated for 10 minutes before the HAE.

4. Statistical Analysis

The data were expressed as mean ± standard error of the mean. Parameters were evaluated using analysis of variance (ANOVA) followed by Tukey’s test with a significance level of p<0.05.

5. Results

In the open field test, administration of HAE induced no changes in peripheral and central locomotion, rearing or defecation when compared to controls (Figure 1A, B, C, D). However, the total time spent in grooming assessed over the 5 minutes observation period in rats treated with a highest

![Figure 1](image-url)
A dose of HAE (2.0g/Kg, n=8) was increased significantly in relation to the control (2.1 ± 2.1s versus 21.5 ± 4.5s, n=7) (Figure 1E). The changes in SBP of normotensive Wistar rats submitted to subacute (7 days) administration of HAE are shown in Figure 2. The HAE 2.0g/Kg (n=5) induced a decrease in SBP from the 1st day of treatment. For the other doses, HAE 0.5 (n=5) and 1.0g/Kg/day (n=5, p.o.) the hypotensive effect was observed only on the 2nd day of treatment and remained constant until the end of the experiment in relation to control group. The last record (7th day) of SBP in each group was 85.6 ± 1.5mmHg; 81.4 ± 1.0mmHg and 82.4 ± 0.3mmHg, corresponding to a decrease by 20%, 24% and 22% respectively, in relation to control (102.9 ± 1.5mmHg) (Figure 2). The analysis of the variations in SBP during the period of treatment of animals with HAE revealed only an oscillation in the response in the 3rd day of administration of HAE 0.5g/Kg/day that it was reversed from the 4th day and maintained until the end of the treatment. For the others doses (1.0 and 2.0g/Kg/day) the treatment for 7 days did not induce a change in SBP established from the 2nd day of treatment (Figure 2).

The chronotropic effect of HAE was studied in the spontaneous beating rate of the right atrium in rats. After equilibration of the atrium for 60 minutes, the heart rate in control group was 145 ± 10.7beats/min (n=3). Addition of HAE 10mg/mL (n=3) produced a negative chronotropic effect inducing a reduction by 90% of spontaneous beating rate in relation to the control. In addition, it was observed that previous incubation (10 minutes) of atropine 1mM did not change the response of HAE, discarding a possible cholinomimetic action of HAE (Figure 3A). Acetylcholine 10µM (n=3) incubated in the absence or presence of the atropine was used as a positive control (Figure 3B).

6. Discussion

The neuropharmacological observation in rats employing open field test revealed that the bioactive compounds present in HAE induced the increase of grooming, a complex innate behavior which involves a series of individual movements that form functional sequences, including highly stereotyped patterns (Kaluff et al., 2016). The investigation of rodent grooming is potentially useful for translational neuroscience research because it may help in understanding the neural mechanisms of motor control besides to provide valuable mechanistic insights into their dysregulation, that may be relevant to elucidation of human brain disorders (Taylor et al., 2010).

Studies of rats decerebrated, in which the mesencephalon is intact, showed normal sequential pattern of grooming, although such animals have difficulty in completing the full pattern. The gradual degradation of the sequential pattern itself is seen in rats that have been decerebrated at more caudal levels, suggesting that the brainstem circuitry is necessary for the execution of fully patterned
grooming sequences (Kalueff et al., 2016). Circuits that incorporate the basal ganglia and allied nuclei, including the striatum, globus pallidus, substantia nigra, nucleus accumbens and subthalamic nucleus, have been strongly implicated in hierarchical motor control and sequencing of grooming. Lesions of the striatum result in a permanent deficit in the ability to complete sequential grooming chains (Kalueff et al., 2016). Other neural structures, such as the neocortex, cerebellum, amygdala and hypothalamus are important brain regions that incorporates neural and endocrine regulation of self-grooming but they are not determine the establishment of the fixed pattern of this behavior (Kalueff et al., 2016).

Grooming sequencing in rodents can be affected by experimental manipulation, including administration of drugs, genetic mutations and psychological stress (Kalueff et al., 2016).

Numerous studies have shown that different agents such as several peptidergic hormones (Gispen and Isaacs, 1981; Isaacs et al., 1983; Jolles et al., 1979) and neurotransmitters, such as dopamine (Taylor et al., 2010; Pelosi et al., 2015; Homberg et al., 2002) and acetylcholine (Gamberini et al., 2012, 2015a), induce grooming in rodents. The pharmacological inductions may show patterns of this behavior with specific topographies to the type of substance administered indicating that different neural mechanisms are involved in the regulation of different patterns of grooming (Bressers et al., 1995a). As shown by the results obtained in the current study, it is unquestionable that pharmacologically active substances present in Campomanesia phaea affect the neural circuits involved with grooming.

In regard to the cardiovascular activity of the plant, the results obtained revealed that the subacute administration of HAE induced hypotension.

The participation of cholinergic pathways in the induction and modulation of neural pathways in the development of grooming is well established (Gamberini et al., 2012, 2015a). Actions related to blood pressure control are also attributed to acetylcholine, such as chronotropic and dromotropic negative responses from the activation of cholinergic M2 receptors present in cardiac cells (Nenasheva et al., 2013). Cholinergic pathways in the vasomotor center, if activated, could also determine blood pressure reduction in animals (Gordan et al., 2015).

Thus, our initial hypothesis to explain the possible mechanism of the hypotensive effect of Campomanesia was that it was due to the cholinomimetic action of bioactive compounds present in the hydro-alcoholic extract obtained from the fruits of the plant. This hypothesis, however, was discarded following the results obtained from the isolated right atrium preparations. In these experiments the negative chronotropic action of HAE was demonstrated, an effect that could partially explain the reduction in the blood pressure values of the animals, but this action was not due to the stimulation of cholinergic receptors, since the non-selective antagonist of cholinergic receptors, atropine, was not able to block the HAE response.

So, the present study was able to reveal pharmacological actions of the hydro-alcoholic extract of Campomanesia phaea fruits on the central nervous and cardiovascular systems in rats, represented by grooming, hypotension and bradycardia, which are not related to a cholinergic response.
