Abstract

The objective of the present study was to investigate the effects of recombinant human growth hormone (rhGH) on the intestinal mucosa barrier of septic rats and explore its possible mechanism. Female Sprague-Dawley rats were randomized into three groups: control, Escherichia coli-induced sepsis (S) and treatment (T) groups. Groups S and T were subdivided into subgroups 1d and 3d, respectively. Expression of liver insulin-like growth factor-1 (IGF-1) mRNA, Bcl-2 and Bax protein levels and the intestinal Bax/Bcl-2 ratio, and plasma GH and IGF-1 levels were determined. Histological examination of the intestine was performed and bacterial translocation was determined. rhGH significantly attenuated intestinal mucosal injuries and bacterial translocation in septic rats, markedly decreased Bax protein levels, inhibited the decrease of Bcl-2 protein expression and maintained the Bax/Bcl-2 ratio in the intestine. rhGH given after sepsis significantly improved levels of plasma GH (T1d: 1.28 ± 0.24; T3d: 2.14 ± 0.48 µg/L vs S1d: 0.74 ± 0.12; S3d: 0.60 ± 0.18 µg/L; P < 0.05) and IGF-1 (T1d: 168.94 ± 65.67; T3d: 201.56 ± 64.98 µg/L vs S1d: 116.72 ± 13.96; S3d: 107.50 ± 23.53 µg/L; P < 0.05) and expression of liver IGF-1 mRNA (T1d: 0.98 ± 0.20; T3d: 1.76 ± 0.17 vs S1d: 0.38 ± 0.09; S3d: 0.46 ± 0.10; P < 0.05). These findings indicate that treatment with rhGH had beneficial effects on the maintenance of the integrity of the intestinal mucosa barrier in septic rats.

Introduction

The intestinal mucosa has metabolic, endocrine and immunologic functions and serves as a major local defense barrier, preventing translocation of bacteria and endotoxins from the gut to extraintestinal tissues and blood (1). It has been shown that impairment of the intestinal mucosa barrier plays a critical role in the initiation of multiorgan dysfunction syndrome, as well as in multiple organ failure. Growth hormone (GH), an anabolic hormone secreted by the anterior pituitary gland, is known to act on the gastrointestinal tract, maintaining the structure and function of intestinal mucosa (1). With a half-life of only 3 h, GH action is mostly mediated by GH-dependent hepatic production of insulin-like growth factor-1 (IGF-1), which has been defined as an important in-
testinal growth factor (2). Both animal and human studies have demonstrated that recombinant human growth hormone (rhGH) can enhance protein synthesis, promote tissue recovery, stimulate intestinal epithelial growth, etc. (3-5). However, the mechanism of the protective effect of rhGH on the intestinal mucosa barrier is not understood.

In the present study, sepsis was induced by intraperitoneal (ip) injection of Escherichia coli. The intestinal mucosa was examined histologically and bacterial translocation, Bcl-2 and Bax protein levels and the Bax/Bcl-2 ratio of the intestine were measured. Plasma GH and IGF-1 levels and expression of liver IGF-1 mRNA were also determined. Thus, the present study was undertaken to investigate the effects of rhGH treatment on the intestinal mucosa barrier of septic rats and to explore the possible mechanism involved.

Material and Methods

Animal models and groups

Female Sprague-Dawley rats weighing 200 to 240 g were obtained from the Animal Center of Sichuan University (Chengdu, China). The experimental protocol was approved by the Animal Care and Scientific Committee of Sichuan University. The rats were randomized into three groups: control group (group C, N = 8), physiological saline alone, ip; sepsis group (group S, N = 17), injected ip with a bolus of ostrich strain E. coli suspension (1 x 10^{10} CFU/L, 15 mL/kg, provided by the Department of Microbiology, West China School of Preclinical and Forensic Medicine, Sichuan University), followed by intramuscular injection of physiological saline, and treatment group (group T, N = 17), which received a bolus administration of E. coli and was treated with an intramuscular injection of rhGH (Saizen, Serono Co., Geneva, Switzerland) (2.25 U kg^{-1} day^{-1}) once a day. Group S was subdivided into S1d (N = 8) and S3d (N = 9) subgroups receiving physiological saline for 1 day or daily for 3 days. Group T was subdivided into T1d (N = 9) and T3d (N = 8) subgroups receiving rhGH for 1 day or daily for 3 days.

Measurement of GH and IGF-1 levels in plasma

Rats were anesthetized with sodium pentobarbital (15 mL/kg, ip). Blood anticoagulated by heparin was harvested through a femoral arterial cannula and then centrifuged to collect plasma. Plasma GH and IGF-1 levels were determined by radioimmunoassy using a kit from Tianjin JiuDing Medicine Bio-Engineering Co., Ltd., Tianjin, China, for GH and a radioimmunoassay kit from Biocode-Hycel Company, Brussels, Belgium, for IGF-1.

Observation of bacterial translocation

Bacterial translocation is a phenomenon characterized by migration of bacteria through the intestinal wall into extra-intestinal tissues, so that bacteria that grow in blood cultures are the same as inside the bowel. In the present study, one drop of blood from the heart was spread on a glass slide and stained with Gram stain. Another 40-µL heart blood sample was incubated on agar plates at 37°C and examined after 24 h. Bacterial colony numbers were counted and the material was spread on a glass slide and stained with Gram stain. A bacteriologist observed the stained results under an oil microscope in a blind fashion.

Histological examinations of the intestinal mucosa

Two-centimeter long ileum specimens were fixed in neutral buffered formalin and embedded in paraffin. Sections (5 µm) were used for standard histological staining with
hematoxylin and eosin and then examined under a light microscope. A pathologist performed all pathologic examinations in a blind fashion. Length and width of intestinal mucosal villi were determined using BI-2000 medicine image analysis software (Chengdu Taimeng Technology Co., Ltd., Chengdu, China).

**Immunohistochemical detection of Bcl-2 and Bax in the intestine**

Immunohistochemical staining for Bcl-2 and Bax was performed by the streptavidin-peroxidase method. Monoclonal Bcl-2 and Bax antibodies were purchased from Santa Cruz Company, Santa Cruz, CA, USA. For the negative control, phosphate-buffered solution was used instead of the primary antibody. Brown granules in the cytoplasm indicated positive expression of Bcl-2 and Bax. These sections were analyzed by light microscopy and photographed. After photographic reconstruction of each tissue section, the photographs were scanned and digitized for computerized analysis with the Image-Pro plus 4.1 software (Media Cybernetics, Inc., Silver Spring, MD, USA). Integral optical density is reported as expression of Bcl-2 and Bax proteins.

**RT-PCR analysis for the expression of liver IGF-1 mRNA**

Total liver RNA was extracted with the Trizol reagent (Tiangen Biol-Tech Co., Ltd., Shanghai, China) and quantified spectrophotometrically. RT-PCR was run using a two-step method. Total RNA was used to synthesize cDNA with the MMuLV RT/PCR reagent kit and then using PCR to amplify cDNA. Rat glyceraldehyde-3-phosphate dehydrogenase (GAPDH), the housekeeping gene, was used as internal control primer. Primer sequences were 5'-ATC ATG TCG TCT TCA CAT CTC TT-3' (upstream primer), 5'-CTA CAT TCT GTA GGT CTT GTT TCC T-3' (downstream primer) for IGF-1, and 5'-CCC ATC ACC ATC TTC CAG GA-3' (upstream primer), 5'-TGC TTC ACC ACC TTC TTG AT-3' (downstream primer) for GAPDH. The PCR products were a 376-bp fragment for IGF-1 and a 574-bp fragment for GAPDH. PCR was performed in a 50-µL reaction volume. A hot start was applied for 4 min at 94°C. The amplification cycle (denaturation step at 94°C for 45 s, an annealing step at 58°C for 45 s and an extension step at 72°C for 1 min) was repeated 25 times. The amplified products of IGF-1 and GAPDH were separated by 1.2% agarose formaldehyde gel electrophoresis stained with ethidium and visualized with UV illumination. The electrophoresis photo was digitized, and IGF-1 and GAPDH band integrated optical density values were analyzed using a Bio-Rad image system (Hercules, CA, USA). Semiquantitative analysis of IGF-1 mRNA was performed by comparison to GAPDH.

**Statistical analysis**

Data are reported as means ± SD except for the rate of bacterial-positive blood smear. Bacterial-positive rates of blood smears were analyzed by the chi-square test. Other experimental results were analyzed statistically by the q test. The results were analyzed using SPSS 11.0 software, with the level of significance set at P < 0.05.

**Results**

**Effects of rhGH on the histological appearance of the intestine**

In group C, the intestinal mucosa structure remained intact, with villi arranged in an orderly manner. In group S, intestinal mucosal villi were edematous, markedly shortened, not uniform in length and arranged in a disorderly manner, and the epithelium was necrotic and markedly and flak-
The lamina propria showed some edema accompanying inflammatory cell infiltration, with these changes being more marked in the S1d group. In group T, the injuries to the intestinal mucosa were markedly attenuated, especially in the T3d group. In group S, the length of intestinal mucosal villi was clearly shortened and their width was clearly increased compared to group C. The length of intestinal mucosal villi was shorter in group T than in group C, but was still significantly longer than that of group S. There was no significant difference in the width of mucosal villi between group T and group C (see Table 1, Figure 1).

Effects of rhGH on intestinal bacterial translocation

Blood smear and bacterial culture were negative in group C. Blood smears from groups S1d and S3d showed 100% bacterial positivity, whereas bacterial positivity was significantly lower in blood smears from groups T1d and T3d. Bacterial colony numbers were markedly lower in blood cultures of groups T1d and T3d compared with group S (see Table 2). Gram staining revealed G+ and G− bacteria in groups S and T. Most bacteria were bacilli such as E. coli, etc. In addition, cocci were also found (see Figure 2).

Effects of rhGH on the levels of Bcl-2 and Bax proteins and the Bax/Bcl-2 ratio in the intestine

As shown in Table 3 and Figure 3, Bcl-2 protein levels in the intestine of group S were obviously lower than in group C (P < 0.05), and more so in group S1d. Bcl-2 protein in the intestine of group T1d was significantly lower than in group C, but was markedly higher than in group S (P < 0.05), and Bcl-2 protein expression showed no significant difference between groups T3d and C (P > 0.05). Compared with groups C and T3d, Bax protein increased markedly in group S3d (P < 0.05). Bax protein expression was clearly decreased in group T3d compared to groups C (P < 0.05) and S (P < 0.05). The Bax/Bcl-2 ratio was significantly higher in group S than in group T (P < 0.05), and more so in group S1d. The Bax/Bcl-2 ratio was clearly higher in group T1d than in group C.

(P < 0.05) and was significantly higher than in group S (P < 0.05). The Bax/Bcl-2 ratio of group T3d returned to the level of group C (P > 0.05).

Effects of rhGH on plasma levels of GH and IGF-1

Compared with groups C (1.18 ± 0.28 µg/L) and T (T1d: 1.28 ± 0.24 µg/L; T3d: 2.14 ± 0.48 µg/L), plasma GH levels declined markedly in groups S1d (0.74 ± 0.12 µg/L) and S3d (0.60 ± 0.18 µg/L; P < 0.05). Plasma GH levels were clearly higher in group T3d than in groups C (P < 0.05) and T1d (P < 0.05). Plasma IGF-1 levels did not differ significantly between group S (S1d: 116.72 ± 13.96 µg/L; S3d: 107.50 ± 23.53 µg/L) and group C (106.63 ± 18.75 µg/L). Compared with groups C (106.63 ± 18.75 µg/L) and S (S1d: 116.72 ± 13.96 µg/L; S3d: 107.50 ± 23.53 µg/L) and S3d (0.60 ± 0.18 µg/L; P < 0.05). The Bax/Bcl-2 ratio of group T3d returned to the level of group C (P > 0.05).

*P < 0.05 compared to control; *P < 0.05 compared to S1d; **P < 0.05 compared to S3d; *P < 0.05 compared to T1d (q test).
107.50 ± 23.53 µg/L), plasma levels of IGF-1 were clearly increase in group T (T1d: 168.94 ± 65.67 µg/L; T3d: 201.56 ± 64.98 µg/L) and especially in group T3d (P < 0.05).

**Effects of rhGH on the expression of liver IGF-1 mRNA**

Expression of liver IGF-1 mRNA was markedly lower in group S1d (0.38 ± 0.09) than in group C (0.64 ± 0.08; P < 0.05). Expression of liver IGF-1 mRNA in group T was clearly higher than in groups C (P < 0.05) and S (S3d: 0.46 ± 0.10; P < 0.05), and more so in group T3d (see Figure 4).

**Discussion**

An important function of the intestinal mucosa barrier is to prevent translocation of bacteria/toxins into the circulation. The maintenance of function of the intestinal mucosa barrier depends upon the integrity of the structure and function of the intestinal mucosa. The present study showed that the integrity of the intestinal mucosa barrier was markedly compromised in septic rats. The results of Gram staining indicated that bacterial translocation occurred in the intestine of septic rats. rhGH administration reduced the injuries to the intestinal mucosa and bacterial translocation in septic rats, suggesting that treatment with rhGH had beneficial effects on the maintenance of the integrity of the intestinal mucosa barrier, as shown in the items below.

**Inhibition of apoptosis.** Bcl-2 is a typical apoptosis suppressor gene, while Bax is a gene that promotes apoptosis. The Bax/Bcl-2 ratio determines whether apoptosis will occur (6). Our data showed that Bcl-2 protein expression was significantly decreased in the intestine of septic rats, while Bax protein expression and the Bax/Bcl-2 ratio were clearly increased in S group, suggesting that epithelial apoptosis was present in the intestinal mucosa of septic rats, in agreement with data reported by Coopersmith et al. (7). An increase of epithelial apoptosis reduces the cell population and causes separation of tight connections, which may be possible causes of impairment of the intestinal mucosa barrier. Baixeras et al. (8) have confirmed that rhGH treatment can inhibit apoptosis. Our results showed that rhGH treatment after sepsis could not only markedly decrease Bax protein levels but also inhibit the decrease of Bcl-2 protein expression and maintain the Bax/Bcl-2 ratio in the intestine, implying that rhGH inhibited apoptosis of the intestinal mucosa epithelium. To some extent, this may be useful to maintain the functions of the intestinal mucosa barrier and to alleviate bacterial translocation in septic rats.

**Effects of rhGH on the GH/IGF-1 axis.** Our data showed that plasma GH levels increased markedly during continuous rhGH administration to septic rats. GH receptors (GHRs) are extensively distributed in the intestinal mucosa. GH binding to GHRs through the ability of the intestinal mucosa to take up and utilize glutamine could promote growth differentiation and wound repair of the intestinal mucosa, ameliorate the impairment of the intestinal mucosa and maintain the structure and function of the intestinal mucosa barrier (9). The GH/IGF-1 axis is present in the body (10-14). GH binding to GHRs could increase IGF-1 lev-

Effects of growth hormone on intestinal mucosal barrier

els, and the biological effects of GH are indirectly mediated by IGF-1 directly acting on target cells (15). IGF-1 is a polypeptide that affects the growth, development and metabolism of a wide variety of cell types and is synthesized and secreted primarily by the liver. Our findings showed that plasma IGF-1 levels increased significantly after treatment with rhGH. The results of RT-PCR also showed that rhGH administration obviously promoted the expression of liver IGF-1 mRNA, indicating that rhGH could enhance plasma IGF-1 levels by promoting the expression of liver IGF-1 mRNA. IGF-1 can stimulate regeneration of the intestinal mucosa and maintain its structure and function (16). Chen et al. (17) demonstrated that IGF-1 can prevent intestinal atrophy in septic rats, protect the integrity of intestinal structure and maintain the function of the intestinal mucosa barrier.

GH is an important anabolic hormone. Some studies have indicated that treatment with GH is safe and beneficial for patients with mild sepsis and severe sepsis, as well as for critically ill patients without sepsis. We have previously demonstrated that rhGH can improve the circulatory function and increase the survival of rats in septic shock (5). However, it has been demonstrated that administration of rhGH to long-stay critically ill adults increases morbidity and mortality (18, 19). At present, the use of rhGH for the treatment of critically ill patients remains controversial and the reason for the varied effects is still unclear.

In the study by Takala’s group (18), higher doses of rhGH were used, while in our study the dose administered to rats was equivalent to half the dose administered to Takala’s patients. We guess that the reason for the increased morbidity and mortality observed in the study by Takala’s group may have been related to dosage. Higher or lower doses of hormone may exert different effects. Higher GH doses may easily result in insulin resistance, hyperglycemia and inhibition of immune function (18). Therefore, we believe that an appropriate dosage of rhGH may be safe and beneficial for critical cases, instead of being harmful.

The present results showed that plasma IGF-1 levels and the expression of liver IGF-1 mRNA were significantly increased in septic rats after treatment with rhGH, indicating that GH resistance in sepsis did not occur. However, Yumet et al. (20) demonstrated reductions in circulating IGF-1 12 and 24 h after rhGH administration in septic rats, suggesting that GH resistance occurred in sepsis. There are two possible explanations for this apparent difference: 1) it might be associated with the sex of rats. In the present study, we selected female rats, while Yumet et al. (20) used male rats. Signal transducers and activators of transcription (STAT5) are required for both basal and GH-induced expression of hepatic IGF-1. The study by Yumet et al. (20) showed that levels of total GHR, Janus kinase (JAK)2, and STAT5 were unchanged in liver from septic rats. However, phosphorylated STAT5 and STAT5 DNA binding were significantly reduced 30 min after GH administration in liver from septic rats. These findings indicated that sepsis reduced STAT5 phosphorylation and activity in liver as well as plasma IGF-1 following rhGH administration. The study by Venken et al. (21) indicated that estradiol restored down-regulated receptor signaling systems, such as the estrogen receptor alpha and the prolactin receptor. Estradiol thereby recovered the JAK/STAT pathway as evidenced by a significantly increased activation of the transcription factor STAT5. In the present study, we used female rats, which mainly secrete estrogen. Estrogen is a major GH-independent regulator of hepatic IGF-1 synthesis (21). We assume that, in septic female rats, estrogen may increase activation of the transcription factor STAT5 and the hepatic IGF-1 gene transcription as well as plasma IGF-1 levels following rhGH administration. 2) The
apparent difference might be related to the dose of rhGH. In the study by Yumet et al. (20), a higher dose of rhGH (1.6 mg/kg) was used, while in our study the dose administered to rats was 2.25 U/kg (0.75 mg/kg), which was equivalent to 1 half the dose administered to rats by Yumet et al. (20). However, the regulation of IGF-I gene expression is controlled by many factors other than JAK/STAT signaling, including the production and activity of transcription factors, recruitment of transcriptional co-activators, IGF-1 mRNA turnover, protein synthesis, and so on. Further studies will be helpful to elucidate the mechanisms involved in the difference.

In conclusion, the present study showed that the integrity of the intestinal mucosa barrier was injured and bacterial translocation occurred in septic rats. Treatment with rhGH exerted beneficial effects by maintaining the function of the intestinal mucosa barrier in septic rats. The possible mechanism might involve the rhGH-inhibited apoptosis of intestinal mucosa cells and the rhGH-maintained intestinal mucosa barrier via the roles of GH and IGF-1.
