Received 11 December, 1998

We derive a system of equations to describe stationary axisymmetric MHD equilibria characterized by toroidal and poloidal flows as well as plasma anisotropy due to strong magnetic field and eventual auxiliary heating methods. The system consists of a nonlinear partial differential equation for the poloidal magnetic flux function and an algebraic Bernoulli-type equation, which relates plasma density with several surface functions. We analyse the ellipticity of the equation and the plasma density bifurcation as the Alfvén-Mach number is changed.

I Introduction

Plasma rotation in tokamaks has been observed during non-ohmic current drive and neutral beam injection when a net momentum is imparted to the plasma [1]–[2]. Plasma rotations with Mach numbers of order unity have been detected in tokamaks at almost all operating regimes both in toroidal and poloidal directions [3]–[4], [5]. Plasma flow has also been observed in reversed-field pinches (RFP) showing a high velocity shear between core and edge plasma rotation [6]. In field-reversed configurations (FRC) strong plasma azimuthal rotation is responsible for an $n = 2$ instability that may destroy plasma confinement [7].

From the point of view of magnetohydrodynamic (MHD) equilibrium theory in the absence of plasma resistivity (ideal theory) magnetic field lines lie on magnetic flux surfaces that rotate rigidly with the plasma according to Alfvén’s theorem [8]. Equilibria are characterized by surface functions $\Gamma$, i.e., $\Gamma$ physical quantities that are constant on nested closed surfaces $\Gamma$ with the topology of tori. Examples of surface functions include the volume enclosed by a toroidal magnetic surface $\Gamma$, the magnetic flux of the poloidal magnetic field component $\Gamma$ and the field line rotational transform.

We will assume that the plasma is in a MHD stationary equilibrium state which means that all partial time derivatives vanish but allow for stationary velocity profiles including plasma flows in toroidal and poloidal directions. The momentum balance equation in this case leads to an equilibrium partial differential equation for the poloidal flux $\Gamma$ which involves other surface functions. Earlier studies to derive an equilibrium equation with plasma flows were conducted by Zehrfeld and Green [9] and Morozov and Solov’ev [10].

Maschke and Perrin [11] in 1980 were able to solve a MHD equilibrium equation for purely toroidal flows in axisymmetric plasmas. In addition to the ideal MHD equations they have made some thermodynamical as-

sumptions: the plasma was taken to be an ideal gas with larger thermal conductivity along the magnetic field lines than across them, so they have considered the plasma temperature as a surface quantity. Situations where the flow is adiabatic allow the use of plasma entropy as a surface quantity instead of the temperature.

There are few analytical or semi-analytical solutions for purely rotating equilibria in the literature for cylindrical [1112] and spherical geometries [14]. The latter configuration turns to be interesting to explore astrophysical plasmas as magnetic stars. All these solutions share some properties: the magnetic axis (degenerate flux surface where the flux is an extremum) is displaced outwards due to the centrifugal effect and the isobaric (constant pressure) surfaces no longer coincide with the flux surfaces.

The problem of combined toroidal and poloidal fluxes has been first addressed by Zehrfeld and Green [9] who assumed simple adiabatic flow. Later Maschke and Perrin [16] have solved such equilibrium equations in the limit of small ratio of poloidal to toroidal magnetic field and small beta. Further developments were due to Kerner and Tokuda [17] and Tasso and Thomoulopoulos [18]. A common feature of all these models is the need of supplementing the partial differential equation for the magnetic flux with a Bernoulli-like algebraic equation for the density which contains several other surface quantities.

Zelazny and collaborators [19] have obtained numerical solutions of the differential and algebraic equations (called EGSS or “extended Grad-Schlüter-Shafranov” system) by using the inverse method and Fourier decomposition. They have observed that the differential equation alternates between elliptic and hyperbolic when the Alfvén-Mach number of the poloidal flow (defined as the ratio between the poloidal flow velocity and the Alfvén velocity relative to the poloidal magnetic field) increases. This fact was already analytically investigated by Hameiri [20] and it is of fundamental importance if a well posed boundary value problem is to be solved. If the equation is not elliptic no closed equilibrium configurations are possible.

So far we have reported studies on isotropic stationary plasmas only. On the other hand, pressure anisotropy due to intense magnetic fields and auxiliary heating methods is an important factor to be taken into account if a general MHD equilibrium equation is to be written down. It is the case for example when the auxiliary heating power in toroidal devices is greater than the ohmic heating power. This possibility was already considered as early as in 1961 for static equilibria [21] but only recently analytical solutions for static and rotating anisotropic plasmas were obtained [1222]. Clemente has found a method to obtain axisymmetric solutions of the MHD equations with plasma anisotropy in terms of the corresponding solutions of the isotropic set of equations for the static or rotating case.

In this paper we present a more general axisymmetric MHD stationary equilibrium model which takes into account both poloidal and toroidal plasma flows as well as pressure anisotropy. Besides the usual surface quantities [the poloidal magnetic flux and current functions] other auxiliary surface functions will be defined. The poloidal magnetic flux nonlinear partial differential equation is complemented with a Bernoulli-type algebraic equation which generalizes that introduced for the isotropic case [191016]. The system reduces to the previously studied cases when anisotropy tend to vanish. We also discuss the ellipticity of the differential equation and study plasma density bifurcations when the Alfvén-Mach number is varied. This could be related to the problem of L-H transition in tokamaks.

This paper is organized as follows: in the second section we outline the basic MHD and thermodynamical equations to be used and the representations for the magnetic and velocity fields in cylindrical coordinates. Section 3 introduces the auxiliary surface quantities necessary in our model and in section 4 an energy theorem is derived. The momentum balance equation is derived in section 5 whereas in section 6 we study some particular cases. Section 7 is devoted to an analysis of the ellipticity of the equation followed by a discussion on plasma density bifurcation. Our conclusions are left to the last section.
II Basic Equations

Let us consider an ideal plasma of electrons and singly charged ions in stationary equilibrium, all partial time derivatives will vanish and nonzero plasma velocity will be allowed. The corresponding ideal anisotropic MHD equations in standard units are

\[ \nabla \cdot (\rho \mathbf{v}) = 0, \]  
\[ \rho (\mathbf{v} \cdot \nabla) \mathbf{v} + \nabla \cdot \mathbb{P} = \mathbf{j} \times \mathbf{B}, \]  
\[ \nabla \times \mathbf{B} = 0, \]  
\[ \nabla \times \mathbf{E} = \mathbf{j}, \]  
\[ \mathbf{E} + \mathbf{v} \times \mathbf{B} = 0, \]

where

\[ \rho = n(m_e + m_i) \]

is the mass density, \( n \) is the particle number density and \( m_e, m_i \) are the electronic and ionic masses, respectively. \( \mathbf{v} \) is the electric field, \( \mathbf{B} \) the magnetic field and \( \mathbf{j} \) the plasma current density, respectively.

If the plasma is subjected to a strong magnetic field and ions have a small Larmor radius with a rapid gyromotion, the pressure tensor \( \mathbb{P} \) may be no longer isotropic. Introducing different plasma pressures: \( p_\perp \) across the magnetic field and \( p_\parallel \) along it, we can introduce the Chew-Goldberger-Low form for the pressure tensor

\[ \mathbb{P} = p_\perp \mathbb{I} + \mathbb{\sigma}_B \mathbf{B} \mathbf{B}, \]

where

\[ \sigma_\perp \equiv \frac{p_\parallel - p_\perp}{B^2} \]

is a measure of pressure anisotropy, \( \mathbb{I} \) is the identity tensor and \( B^2 = \mathbf{B} \cdot \mathbf{B} \).

In order to get to a closed system of equations we must introduce some constitutive thermodynamical assumption so as to obtain an energy equation. In earlier works where the pressure was supposed isotropic it has been assumed that either the entropy \( S \) or the temperature \( T \) are surface quantities. In the former case an adiabatic equation of state has been used

\[ p p^{-\gamma} = A(S), \]

where \( \gamma \) is the specific heat ratio. The specific enthalpy \( h \) satisfies the thermodynamical relation

\[ dh = T dS + \frac{1}{\rho} dp, \]

which gives by integration using (10)

\[ h = \frac{\gamma}{\gamma - 1} A(S) p^{\gamma - 1}. \]

The internal energy \( \epsilon = h/\gamma \) satisfies the Gibbs’ equation

\[ d\epsilon = T dS + \frac{p}{\rho} \frac{\gamma - 1}{\gamma - 1} dp, \]

so that

\[ T \nabla S = \frac{\rho^{\gamma - 1}}{\gamma - 1} \nabla A(S). \]

In the case of anisotropic pressure, however, we must use the double adiabatic equations

\[ \mathbf{v} \cdot \nabla \ln p_\parallel - \mathbf{v} \cdot \nabla \ln \rho + \frac{2\mathbf{B} \cdot [(\mathbf{B} \cdot \nabla) \mathbf{v}]}{B^2} = 0, \]

\[ \mathbf{v} \cdot \nabla \ln p_\perp - 2\mathbf{v} \cdot \nabla \ln \rho - \frac{\mathbf{B} \cdot [(\mathbf{B} \cdot \nabla) \mathbf{v}]}{B^2} = 0. \]
Using (1)\(\Gamma(5)\) and (6) these equations can be combined there resulting that
\[
\nabla \cdot \left( \frac{\rho p^2}{\rho^4} \mathbf{v} \right) = 0, \tag{17}
\]
\[
\nabla \cdot \left( \frac{p}{|\mathbf{B}|} \mathbf{v} \right) = 0, \tag{18}
\]
\[
\nabla \cdot \left( \frac{p B^2}{\rho^2} \mathbf{v} \right) = 0. \tag{19}
\]

Let us consider cylindrical coordinates \((r, \phi, z)\) where \(\phi\) is an ignorable quantity, i.e., our configuration exhibits symmetry with respect to this coordinate. A magnetic field representation satisfying Eq. (3) can be written in terms of two scalar surface functions \(\Psi\) and \(I\) (poloidal flux and current functions respectively)
\[
\mathbf{B}(r, z) = \nabla \Psi(r, z) \times \frac{\hat{\phi}}{r} + I(r, z) \frac{\hat{\phi}}{r}. \tag{20}
\]
We also assume that the plasma can have a rotation around the symmetry axis in both toroidal and poloidal directions. A velocity representation which satisfies Eq. (1) is
\[
\rho \mathbf{v}(r, z) = \nabla F(r, z) \times \frac{\hat{\phi}}{r} + \rho \Gamma(r, z) \frac{\hat{\phi}}{r}, \tag{21}
\]
where \(\Gamma\) is a stream function and \(F\) is the corresponding stream function for poloidal flow.

### III Auxiliary Surface Quantities

Taking the cross product between (21) and (20)\(\Gamma\) and using axisymmetry we have
\[
\rho (\mathbf{v} \cdot \nabla) \mathbf{v} + \nabla p_\perp + \nabla \cdot (\sigma_\perp \mathbf{B} \mathbf{B}) = (\nabla \times \mathbf{B}) \times \mathbf{B}, \tag{25}
\]
where we have used Ampère’s law (4). Rearranging terms we have
\[
\nabla \left( p_\perp + \frac{B^2}{2} \right) + \nabla \cdot \mathbb{T} = 0, \tag{26}
\]
where we defined the tensor
\[
\mathbb{T} = (\sigma_\perp - 1) \mathbf{B} \mathbf{B} + \rho \mathbf{v} \mathbf{v}. \tag{27}
\]

From Ohm’s law the azimuthal component of Eq. (6) vanishes. Using (22)\(\Gamma\) it implies that the Jacobian of the transformation \((r, z) \rightarrow (F, \Psi)\) is identically zero, i.e., \(\nabla F = F(\Psi)\) is also a surface function. Hence \(\nabla F = F' \nabla \Psi \Gamma\) where the primes denote differentiation with respect to \(\Psi\).

Now inserting (22) into Faraday’s law Eq. (5)\(\Gamma\) and using (6)\(\Gamma\) we obtain \(\nabla \Omega \times \nabla \Psi = 0\) where we have defined
\[
\Omega(\Psi) = \frac{\Gamma}{r^2} - \frac{1}{\rho r^2}, \tag{23}
\]
and it is also a surface quantity. Physically \(\Omega(r, z)\) is a toroidal angular velocity for a rigid surface rotation. This is commonly called “Ferraro’s isorotation law” [8].

Combining (23) with (21) we have for the plasma velocity the following expression in terms of the magnetic field
\[
\mathbf{v}(r, z) = \frac{F'}{\rho} \mathbf{B}(r, z) + \Omega r \hat{\phi}. \tag{24}
\]

Computing the divergence of the pressure tensor \(\Gamma\) as given in the form (8)\(\Gamma\) and substituting it into the momentum balance equation for equilibria Eq. (2)\(\Gamma\) we have
\[
\rho (\mathbf{v} \cdot \nabla) \mathbf{v} + \nabla p_\perp + \nabla \cdot (\sigma_\perp \mathbf{B} \mathbf{B}) = (\nabla \times \mathbf{B}) \times \mathbf{B}, \tag{25}
\]

Dotting (26) with \(\hat{\phi}\)\(\Gamma\) we find that the divergence of \(\mathbb{T}\) has zero \(\phi\)-component. There results by using (1) and (2)\(\Gamma\) that (25) can be rewritten as
\[ \mathbf{B} \cdot \nabla \left[ r (\sigma_+ - 1) B_\phi \right] + \rho \mathbf{v} \cdot \nabla (\nu v) = 0, \]  
(28)

or by means of the assumed representations of \( \mathbf{B} \) and \( \mathbf{v} \Gamma \)
\[ \mathbf{B} \cdot \nabla \left[ (\sigma_+ - 1) I + F' \Gamma \right] = \mathbf{B} \cdot \nabla \Lambda = 0, \]  
(29)

where a new auxiliary surface quantity has been defined as
\[ \Lambda (\Psi) = (\sigma_+ - 1) I + F' \Gamma. \]  
(30)

Let us discuss a special case in order to get a physical insight on the possible motions allowed by the present treatment. In the case of a field-reversed configuration (FRC) we have \( I = 0 \) so \( \Gamma = \Lambda / F' \). On the other hand from (23) we have that \( \Gamma = \Omega r^2 \). However while \( \Lambda / F' \) is a surface quantity it is easy to prove that \( \Omega r^2 \) is not. Hence the equality
\[ \frac{\Lambda}{F'} = \Omega r^2 \]  
(31)

is not valid for both \( \Lambda \neq 0 \) and \( F' \neq 0 \).

Therefore there are only two cases where the equality (31) is compatible with (30) in the a FRC case: i) \( \Omega \neq 0 \) and \( F' = \Lambda = 0 \) which means only azimuthal rotation (toroidal plasma flow); or ii) \( \Omega = \Gamma = 0 \) and \( F' \neq 0 \) i.e. only poloidal flow. Since in FRC some region of vanishing magnetic field where \( \sigma_- \) should vanish.

\[ \mathbf{E} \cdot \mathbf{j} = \rho \mathbf{v} \cdot [\mathbf{v} \cdot \nabla] + \mathbf{v} \cdot \mathbf{v} p_\perp + \mathbf{v} \cdot [\mathbf{B} (\mathbf{B} \cdot \nabla \sigma_-)] + \sigma_- \mathbf{v} \cdot [\mathbf{B} (\mathbf{B} \cdot \nabla \mathbf{B})]. \]  
(33)

Using the double adiabatic equations (15 and 16) this term can be rewritten after some algebra in the form of an energy theorem for anisotropic stationary equilibria
\[ \nabla \cdot \left[ \left( \frac{p_\parallel}{2 \rho} + \frac{2 p_\perp}{\rho} + \frac{v^2}{2} \right) \rho \mathbf{v} + \sigma_- \mathbf{B} (\mathbf{B} \cdot \mathbf{v}) + \mathbf{E} \times \mathbf{B} \right] = 0. \]  
(34)

Now using (20) and (6) we have for the divergence of the Poynting vector
\[ \nabla \cdot (\mathbf{E} \times \mathbf{B}) = - F' \mathbf{B} \cdot \nabla \left( \frac{\Omega I}{F'} \right), \]  
(35)

and considering that
\[ \nabla \cdot [\sigma_- \mathbf{B} (\mathbf{B} \cdot \mathbf{v})] = \mathbf{B} \cdot \nabla \left[ \frac{F'(p_\parallel - p_\perp)}{\rho} \right] + \mathbf{B} \cdot \nabla (\Omega I \sigma_-), \]  
(36)
we have that Equation (34) implies the following relation

\[ \mathbf{B} \cdot \nabla \left[ \frac{3p_\parallel}{2\rho} + \frac{p_\perp}{\rho} + \frac{v^2}{2} - \frac{\Omega I}{F'} (1 - \sigma_-) \right] = 0, \tag{37} \]

and we see that the expression within the brackets is a surface quantity

\[ \Theta(\Psi) \equiv \frac{3p_\parallel}{2\rho} + \frac{p_\perp}{\rho} + \frac{v^2}{2} - \frac{\Omega I}{F'} (1 - \sigma_-) \]

\[ = \frac{3p_\parallel}{2\rho} + \frac{p_\perp}{\rho} + \frac{F'^2 B^2}{2p^2} - \frac{\Omega^2 r^2}{2}. \tag{38} \]

since \( \mathbf{B} \cdot \nabla \Theta = 0 \). This is a Bernoulli-type algebraic equation that implicitly defines the plasma density \( \rho \) in this double adiabatic model.

V Momentum balance equation

Consider the equation of motion (2) rewritten by using Ampère’s law (4) and opening the divergence of pressure tensor given by (8). It reads

\[ \rho (\mathbf{v} \cdot \nabla) \mathbf{v} + \nabla p_\perp + (\nabla \sigma_-) \cdot (\mathbf{B} \mathbf{B}) + \sigma_- \left[ (\nabla \times \mathbf{B}) \times \mathbf{B} + \nabla \left( \frac{B^2}{2} \right) \right] = (\nabla \times \mathbf{B}) \times \mathbf{B}. \tag{39} \]

The first term in the left-hand side can be written as

\[ \rho \left[ (\nabla \times \mathbf{v}) \times \mathbf{v} + \nabla \left( \frac{v^2}{2} \right) \right]. \]

Dotting it with \( \nabla \Psi \Gamma \) and using the representation (24) for the velocity we have

\[ \nabla \Psi : [\rho (\mathbf{v} \cdot \nabla) \mathbf{v}] = \frac{F'^2}{\rho} \nabla \Psi \cdot \left[ \nabla \left( \frac{B^2}{2} \right) + (\nabla \times \mathbf{B}) \times \mathbf{B} \right] - \frac{F' \Omega I}{r^2} \nabla \Psi \cdot \nabla r^2 - \rho \Omega^2 \nabla \Psi \cdot \nabla \left( \frac{r^2}{2} \right). \tag{40} \]

Similarly the term involving the pressure tensor would give

\[ \nabla \Psi \cdot \nabla p_\perp + \sigma_- \nabla \Psi \cdot \left[ \left( \nabla \left( \frac{B^2}{2} \right) + (\nabla \times \mathbf{B}) \times \mathbf{B} \right) \right]. \tag{41} \]

The calculation of the last term is analogous to the static axisymmetric case and reads

\[ \nabla \Psi : [(\nabla \times \mathbf{B}) \times \mathbf{B}] = -\Delta^* \Psi \frac{[\nabla \Psi]^2}{r^2} - \frac{r^2}{r^2} \cdot \nabla \Psi \nabla \Psi, \tag{42} \]

where the Grad-Shafranov operator \( \Delta^* \) is given by

\[ \Delta^* \Psi = r^2 \frac{\partial}{\partial r} \left( \frac{1}{r^2} \frac{\partial \Psi}{\partial r} \right) + \frac{\partial^2 \Psi}{\partial \phi^2}. \tag{43} \]

Plugging eqs. (40)(41) and (42) into (39) and after some rearrangements we have the equation

\[ \left( 1 - \frac{F'^2}{\rho} - \sigma_- \right) \Delta^* \Psi = -r^4 \rho \Omega I' - IA' - r^2 (F' \Omega)' I - \frac{r^2}{|\Psi|^2} \nabla \Psi \cdot \left[ -\frac{F'^2}{\rho} + \sigma_- \right] \nabla p_\perp + \left( \frac{F'^2}{\rho} + \sigma_- \right) \nabla \left( \frac{B^2}{2} \right) - \rho \nabla \left( \frac{\Omega^2 r^2}{2} \right). \tag{44} \]
But using (23) we have that
\[
\nabla \left( \frac{F'^2}{\rho} \frac{B^2}{\rho} - \frac{\Omega^2 r^3}{2} \right) = \Theta \nabla \Psi - \nabla \left( \frac{3p||}{2\rho} + \frac{p_\perp}{\rho} \right), \tag{45}
\]
and substituting it in (44) we have
\[
\begin{align*}
&\left(1 - \frac{F'^2}{\rho} - \sigma_- \right) \Delta \Psi = -r^4 \rho \Omega' - 4 \Lambda' - r^3 (F' \Omega') I - r^2 \rho \Theta' + \\
&+ F'^2 \frac{F''}{\rho} + F' \nabla \Psi : \nabla \left( \frac{F'}{\rho} \right) + \\
&+ \frac{(\nabla \Psi, \nabla \sigma_-)}{\|\Psi\|^2} \nabla \Psi : \left[ \sigma_- \nabla \left( \frac{B^2}{2} \right) + \nabla p_\perp + B^2 \nabla \sigma_- - \rho \left( \frac{3p||}{2\rho} + \frac{p_\perp}{\rho} \right) \right].
\end{align*}
\tag{46}
\]

The term within brackets in the second member of the above equation may be written as
\[
- p_\perp \frac{\nabla g}{g} - \frac{p||}{2} \frac{\nabla f}{f},
\tag{47}
\]
where we have defined
\[
g \equiv \frac{p_\perp}{\rho B}, \quad f \equiv \frac{p|| B^2}{\rho^2}.
\tag{48}
\]

Using the double adiabatic equations (17Π8Π9) we can show that \(f\) and \(g\) are actually surface quantities so that we finally get to the momentum balance equation describing stationary MHD equilibrium of an axisymmetric plasma with anisotropy and general flow
\[
\begin{align*}
&\left(1 - \frac{F'^2}{\rho} - \sigma_- \right) \Delta \Psi = -r^4 \rho \Omega' - 4 \Lambda' - r^3 (F' \Omega') I - r^2 \rho \Theta' + \\
&+ F'^2 \frac{F''}{\rho} + \nabla \Psi : \left[ F' \nabla \left( \frac{F'}{\rho} \right) + \nabla \sigma_- \right] + r^2 \left( p_\perp \frac{g'}{g} + \frac{p||}{2} \frac{f'}{f} \right). \tag{49}
\end{align*}
\]

Equation (49) together with (38) form a set of coupled equations whose solutions depend on six hypotheses on the functional dependence with \(\Psi\) of the surface quantities \(\Omega, F', f, g, \Lambda\) and \(\Theta\).

\section{VI Particular cases}

Once we have obtained the general equations for anisotropic equilibria with plasma flows let us consider some special cases. First we consider the isotropic case where we have \(p_\perp = p|| = p\Gamma\) or \(\sigma_- = 0\). In this case the term
\[
p_\perp \frac{g'}{g} + \frac{p||}{2} \frac{f'}{f}
\tag{50}
\]
in Equation (49) may be written as
\[
\frac{3}{2} \rho \left[ \ln \left( \rho p^{-5/3} \right) \right]', \tag{51}
\]
or identifying \(\gamma = 5/3\) and using the adiabatic law (10) as
\[
\frac{\rho^{\gamma-1} dA}{\gamma - 1 d\Psi} \tag{52}
\]
The equation (49) for isotropic plasmas (simple adiabatic model) assumes the form
Making the following changes of notation: \( I \rightarrow I \Gamma \Omega \rightarrow \omega \Gamma F' \rightarrow u \Gamma \Theta \rightarrow \Theta \Gamma \Delta^* \rightarrow \mathcal{L} \Gamma \Psi \rightarrow \psi \Gamma \) and \( \Lambda \rightarrow I_3 + \Lambda_1 \) we get to the equation presented by Maschke and Perrin [16] for toroidal and poloidal fluxes which to be supplemented by the Bernoulli-type equation (38) which in this limit reduces to

\[
\Theta(\Psi) = \frac{\gamma}{\gamma - 1} \rho^{\gamma - 1} + \frac{1}{2} \frac{\rho'^2}{\rho} \left( \frac{I^2 + |\nabla \Psi|^2}{r^2} \right) - \frac{\Omega^2 \rho^2}{2}. \tag{54}
\]

The electric field is \( E = -\nabla \Phi_E \Gamma \) in which the electric potential is also a surface quantity \( \Gamma \) and it is easy to prove that \( \Phi_E(\Psi) = \Omega \).

We can further simplify things by switching off the poloidal flux by making \( F' = 0 \) in (53) with both \( \Gamma \) and \( \Omega \) non-vanishing and isotropic pressure. In this case, using (30) we have that \( \Lambda = I \Gamma \) which is the poloidal current flux. The stationary equilibrium equation becomes

\[
\Delta^* \Psi + I I' + r^4 \rho \Omega' = -r^2 \rho \left( \Theta' - \frac{\rho^\gamma - 1}{\gamma - 1} \right), \tag{55}
\]

where the surface function

\[
\Theta(\Psi) = \frac{\gamma}{\gamma - 1} \rho^{\gamma - 1} - \frac{\Omega^2 \rho^2}{2} = \frac{\Omega^2 \rho^2}{2} \tag{56}
\]

is nothing but the plasma enthalpy (12) with a sort of centrifugal correction. Using the thermodynamical relation (14) we rewrite Eq. (55) in the form

\[
\Delta^* \Psi + I I' + \rho^2 \left( r^2 \Omega' + \Theta' - T S' \right) = 0, \tag{57}
\]

which can be identified with the earlier equation of Maschke and Perrin [11] for description of pure toroidal flows with the entropy \( S \) as a surface quantity \( \Gamma \) by making the following changes of notation: \( I \rightarrow \mathcal{J} \Gamma \Omega \rightarrow \omega \Gamma \Theta \rightarrow \theta \Gamma \Delta^* \rightarrow \mathcal{L} \Gamma \Psi \rightarrow \mathcal{F} \Gamma \) and \( r \rightarrow R \). We remark that an equation in which the plasma temperature \( T \) would be a surface function cannot be derived from an adiabatic model such as used here.

Finally, in the limit of vanishing flow \( \Gamma \) we have that \( \rho' = \rho(\Theta' - T S') \Gamma \) with \( \Theta(\Psi) = h \Gamma \) so the equation is simply the Grad-Schlüter-Shafranov equation for the static axisymmetric case

\[
\Delta^* \Psi = -I I' + r^2 \rho'. \tag{58}
\]

VII Ellipticity of the equilibrium equation

Let us return to the set of equations characterizing a general stationary MHD equilibrium with anisotropic pressure and poloidal and toroidal flows. It consists of a nonlinear partial differential equation for the poloidal magnetic flux \( \Psi \Gamma \) Eq. (49) \( \Gamma \) and an algebraic Bernoulli equation (38) \( \Gamma \) which defines the plasma density \( \rho \).

An important issue formerly discussed by Hameiri [20] in the case of isotropic pressure and simple adiabatic flow \( \Gamma \) are the conditions of ellipticity for the partial differential equation. In this case one has to analyse the coefficients of the second order derivatives of \( \Psi \) in Equation (49). This is important because if the equation is elliptic a boundary value problem may be posed after defining proper boundary conditions at the plasma boundary and/or external conductors. In such case it
is possible to solve it by using standard numerical (or, hopefully, analytical) techniques as done by Zelazny and collaborators [19] in the isotropic case. Otherwise, the existence of hyperbolic regimes implies that some kind of shock wave should be generated in the plasma and no closed equilibrium would be possible.

Second-order derivatives (with respect to \( r \) and \( z \)) appear in (49) both in the term containing the Grad-Shafranov operator \( \Delta^* \Psi \) and in the term formed by the dot product of \( \nabla \Psi \) with \( F' \nabla (F'/\rho) + \nabla \sigma_- \). So we may write the quadratic form

\[
\mathcal{L} = A \frac{\partial^2 \Psi}{\partial r^2} + B \frac{\partial^2 \Psi}{\partial z^2} + 2C \frac{\partial^2 \Psi}{\partial r \partial z},
\]

where the coefficients \( A, B, C \) depend on \( |\nabla \Psi|^2 F' / \rho \) and \( \sigma_- \). The determinant of the symmetric matrix of these coefficients is

\[
\text{Det} = AB - C^2.
\]  

Equation (49) will be elliptic if \( \text{Det} > 0 \); parabolic if \( \text{Det} = 0 \); and hyperbolic if \( \text{Det} < 0 \).

Considering the corresponding terms in (49) there results

\[
\text{Det} = (1 - \epsilon)^2 \left( 1 - \frac{2Q |\nabla \Psi|^2}{1 - \epsilon} \right),
\]

where we defined

\[
\epsilon = \frac{F^2}{\rho} + \sigma_-.
\]

and after using (8) and (23) we introduced

\[
Q = \left( 3\beta_\parallel - \beta_\perp - \frac{F' / \rho}{3} \right) \frac{\dot{\rho}}{\rho} - \frac{(\dot{B}^2)}{2B^2} (4\beta_\parallel - \beta_\perp),
\]

where

\[
\beta_\parallel = \frac{p_\parallel}{B^2}, \quad \text{and} \quad \beta_\perp = \frac{p_\perp}{B^2},
\]

and the dots represent differentiation with respect to \( |\nabla \Psi|^2 \).

Now using the Bernoulli equation (38) and after a lengthy but straightforward calculation we find that the determinant is

\[
\text{Det} = (1 - \epsilon)^2 \left[ \frac{1 - \epsilon - X}{1 - \epsilon - X (1 - |\nabla \Psi|^2 / r^2 B^2)} \right],
\]

where

\[
X = \frac{(3\beta_\parallel - \beta_\perp - \frac{F' / \rho}{3})^2}{3\beta_\parallel - \frac{F' / \rho}{3}} - 4\beta_\parallel + \beta_\perp.
\]

If \( \sigma_- = 0 \) the determinant (65) coincides with that formerly derived by Hameiri for isotropic pressure [20].

For large aspect Tokamak equilibria the poloidal field component \( |\nabla \Psi| / r \) is small when compared to the total magnetic field \( B \). If the plasma betas (64) (ratios between kinetic and magnetic pressures) are also small enough we can develop the denominator of \( \text{Det} \) to the first order in \( \frac{|\nabla \Psi|^2}{r^2 B^2}, \beta_\parallel \Gamma \) and \( \beta_\perp \).

There results in this case that \( \text{Det} \) is positively definite when the following conditions hold
As in the simple adiabatic case we have three regions of ellipticity for the parameter $F^2$ which can be interpreted as the square of the poloidal Alfvén Mach number. We note that the second region is separated from the first one by a very small gap.

We stress that plasma density in the present double adiabatic model is implicitly determined by the Bernoulli equation. Substituting there the double adiabatic equations we find after using the definitions of $f$ and $g$ provided by (48) two auxiliary equations for the density:

\[
3\beta || = \frac{\beta^2}{1 + 2\beta \perp} \left( 1 - \frac{[\nabla \Psi]^2}{r^2 B^2} \right) \quad 0 < \frac{F^2}{\rho} < \frac{\beta^2}{1 + 2\beta \perp} \quad (67)
\]

\[
1 - \beta || + \beta \perp < \frac{F^2}{\rho} < 1 - \beta || + \beta \perp \quad (68)
\]

\[
1 - \beta || + \beta \perp < \frac{F^2}{\rho} < \frac{\beta^2}{1 + 2\beta \perp} \quad (69)
\]

where it must be taken into account that $B$ depends also on $\rho$. The plus or minus sign distinguishes different branches for $\rho$. Their equivalence defines one of the bifurcation points for the density.

Using the expression (38) for $\Theta$ of the vanishing of the square root in (70) defines a bifurcation point for the density corresponding to

\[
\frac{3\rho^2}{B^2} = \Theta + \frac{\Omega^2 r^2}{2} - g B \pm \sqrt{\left( \Theta + \frac{\Omega^2 r^2}{2} - g B \right)^2 - 3f F^2} \quad (70)
\]

where the Alfvén Mach number was taken as the bifurcation parameter. As it can be seen from the ellipticity conditions such bifurcation point falls just inside of the second region of ellipticity for the nonlinear partial differential equation for the poloidal magnetic flux. Its connection with an eventual transition similar to the L-II transition in tokamaks (where an abrupt change from low density to high density equilibria is observed when the power of neutral beam injection is increased) is quite suggestive.

\[
F^2 = 3\beta ||, \quad (71)
\]

\[
\frac{F^2}{\rho} = 3\beta ||, \quad (71)
\]

VIII Conclusions

Plasma rotation in fusion plasmas generated in Tokamaks and Reversed Field Pinches is a subject of growing interest since it should be related to the existence or not of equilibrium configurations as well as the presence of some types of instabilities. Hence it would be necessary to develop theoretical models to describe the main effects of rotation without resorting to direct numerical 3-D MHD computer simulations. This can be done by using a double adiabatic ideal MHD model with axisymmetry which includes plasma flow in both poloidal and toroidal directions and pressure anisotropy which are possible conditions in the present generation of strong power injection and high magnetic field tokamaks.

Our theoretical model in accordance with previous approaches with less generality is constituted by a non-

\[
\frac{3\rho^2}{B^2} = \Theta + \frac{\Omega^2 r^2}{2} - g B \pm \sqrt{\left( \Theta + \frac{\Omega^2 r^2}{2} - g B \right)^2 - 3f F^2} \quad (70)
\]

\[
\frac{F^2}{\rho} = 3\beta ||, \quad (71)
\]
linear partial differential equation for the poloidal magnetic flux plus an algebraic Bernoulli-type equation which involves thermodynamical assumptions. The system of equation reduces to the previously studied cases in the appropriate limits of vanishing anisotropy and/or plasma flows.

The differential equation involves six surface quantities which depend on the poloidal flux so in order to obtain a solution hypotheses should be specified for all these functions. However, before proceeding to a solution, hypotheses should be specified for all quantities which depend on the poloidal flux, plus an algebraic Bernoulli-type equation for the poloidal magnetic flux, and anisotropy is considered. Hence, the general equations here derived cannot be used in such cases without proper modifications. However, for tokamaks the theory should work.

Another result is concerned with the definition of plasma density which is implicitly fixed by Bernoulli equation. Our analysis shows the existence of two branches of density characterizing a density bifurcation when the poloidal Alfvén-Mach number varies continuously. The critical bifurcation parameter is located in one of the three ellipticity regions.

This could be related to the transition between a L-mode to H-mode observed in present tokamaks with high power neutral beam injection which is characterized by a sudden increase in the plasma density and improved confinement leading to a better performance. In spite of intense theoretical effort the L-H transition in Tokamaks is poorly understood so our results could shed some light on this subject indicating that the combined action of pressure anisotropy and plasma flows could be the triggering mechanism for the transition to the H-mode regime. However, further work has to be done in order to give more precise answers to this question.

Even for low beta tokamaks our general system of equation seems to be too difficult to allow an analytical solution even using very simple profiles for the surface functions. However, provided we stay within the ellipticity intervals a numerical solution could be sought for after defining proper boundary conditions at the plasma boundary and external conductors. This is beyond the scope of the present paper.
