The occurrence of squeezing effects in coupled oscillators and the transference between them has been studied in various situations using Hamiltonians involving either nonlinear terms or time-dependent parameters. We consider a simplified scheme generating this effect and discuss its origin.

I Introduction

Extensive study of squeezing has been developed since the last decade, both theoretically [1] and experimentally [2]. States of oscillators and single-mode of electromagnetic fields exhibiting this effect were named: squeezed states (Hollenhost [1]); two-photon coherent states (Yuen [1]); generalized coherent states (Sculer [1]); sub-fluctuant states (Glauber and Levenstein [3]); etc. They are nonclassical states, having reduced dispersion in one field-quadrature in comparison with that found in coherent states or vacuum state. Investigations of squeezing have been implemented in various contexts, e.g., considering the system composed by two interacting oscillators, where: (i) one of them has a time-dependent parameter, hence the squeezing effect is generated in such oscillator, its transference to the other oscillator being considered [4, 5, 6]; (ii) one of the oscillators is nonlinear, e.g., quadratic in the annihilation operator $a$ and the creation operator $a^+$, hence squeezing is created in this oscillator [1] its transference to the second (linear and $t$-independent) oscillator being studied, including optimization of this transference [7]; (iii) both oscillators are quadratic in $a$ and $a^+$, this being an extension of the approach presented in [7], as shown in Ref. [8]; (iv) both oscillators are linear and have no $t$-dependent parameter, but the coupling between them is $t$-dependent [9]. In all these cases the effect may refer either to 1-mode squeezing [1] or 2-mode squeezing [10], the first scenario concerning with individual variables (e.g., the in a variance of a single oscillator); and the second scenario with collective variables (e.g., the effect in either the CM-coordinate or in the RELATIVE-coordinate[10]).

To our knowledge, no mention in the literature has been done about the occurrence of one-mode squeezing in coupled linear oscillators, having no $t$-dependence, the scenario seeming to be confined just to the case of two-mode squeezing. In this paper we will show that this is not always true, the result depending on the type of the interaction between the oscillators.

This report is organized as follows: In the Sect. II we present a brief summary of useful definitions and Hamiltonian-schemes employed previously in the literature. Sect. III is about the present model and calculations yielding our results. Sect. IV contains the comments and conclusion.

II Hamiltonian-models for coupled oscillators

In Ref.[6] the following model was employed to investigate the generation and transference of squeezing from
one oscillator to the other:
\[ H = H_Q(a, a^+) + H_L(b, b^+) + V, \]  
(1)
where \( H_Q \) is a quadratic Hamiltonian describing the first oscillator
\[ H_Q = \hbar \omega (a a^* + \frac{1}{2}) + \hbar f(a^{*2} + a^2), \]  
(2)
\( H_L \) is a linear Hamiltonian describing the second oscillator,
\[ H_L = \hbar \omega (b b^* + \frac{1}{2}), \]  
(3)
and \( V \) stands for their interaction, assumed in Ref.[6] as usually
\[ V = \hbar \lambda (a b^* + a^* b), \]  
(4)
where \( \lambda \) is the coupling constant.

This form of interaction corresponds to what is called Rotating-Wave-Approximation (RWA), encountered in studies involving atom-field interaction. In this case the complete atom-field interaction in the Jaynes-Cummings model [11] reads [12]
\[ V' = \hbar \lambda \rho E = \hbar \lambda (a a^*) + (\sigma^+ + \sigma^-) = \hbar \lambda (a a^* + a^* a) \]  
(5)
where \( \rho \sim (\sigma^+ + \sigma^-) \) is the atomic dipole operator and \( E \sim (a a^*) \) is the electric field operator.

Neglecting the counter-rotating term \( \hbar \lambda (a a^* + a^* a) \) leads to a good approximation when the condition \( \lambda \sqrt{\rho} < < 1 \) is satisfied [13], with \( \rho \) being the mean excitation number. In terms of quadrature operators \( \{x_1, p_1\}, \{x_2, p_2\} \), given by
\[ x_1 = (a + a^*)/2, \quad p_1 = (a - a^*)/2i \]  
(6)
\[ x_2 = (b + b^*)/2, \quad p_2 = (b - b^*)/2i \]  
(7)
the interaction in Eq.(4) results in the form
\[ V = \hbar \lambda (x_1 x_2 + p_1 p_2). \]  
(8)

In Refs.[7, 8] it was shown that the squeezing effect generated in the quadratic oscillator can be transferred to the linear oscillator. For interesting details, as the mathematical procedure and optimization of such squeezing transfer, the reader is referred to [7, 8].

On the other hand, in Ref.[9] a different scheme was employed: both oscillators are linear, the squeezing effect emerging from the \( t \)-dependence of the coupling between them. In this case the Hamiltonian was modelled as follows [9]:
\[ H = \frac{1}{2} \hbar \sum_i (p_i^2 + x_i^2) + \hbar \lambda(t) x_1 x_2. \]  
(9)

Note that the interaction in Eq.(9) can be written in the form
\[ V = \hbar \lambda(t) (a b^* + a^* b) + \hbar \lambda(t) (a b + a^* b^*), \]  
(10)
where the Eqs.(6, 7) have been used. For comparison, note also that an alternative interaction to that used in Eq.(9) is
\[ V = \hbar \lambda(t) p_1 p_2. \]  
(11)

In this case, application of Eqs.(6, 7) gives
\[ V = -\hbar \lambda(t) (a b^* + a^* b) + \hbar \lambda(t) (a b + a^* b^*). \]  
(12)

A comparison of Eq.(10) and Eq.(12) shows a difference in the signals accompanying their rotating terms \( (a b^* + a^* b) \). On the other hand, the interaction used in Refs.[7, 8] did not include the counter-rotating term \( (a b + a^* b^*) \). So, in this case the difference is more evident. It is interesting to mention that the rotating-wave term in Eqs.(10, 12), written in terms of \( x_i, p_i \), results
\[ a b^* + a^* b = 2(x_1 x_2 + p_1 p_2), \]  
(13)
whereas the counter-rotating part in these equations reads, in terms of \( x_i \) and \( p_i \),
\[ a b + a^* b^* = 2(x_1 x_2 - p_1 p_2). \]  
(14)

Note that Eqs.(13, 14) are consistent with the Eqs.(9, 10) and Eqs.(11, 12).

Distinct kinds of interactions lead to different results, e.g., variances exhibiting one-mode squeezing, or not. Here we will employ a convenient form in these alternatives to verify the occurrence of squeezing in our system.

III The interaction model

\[ V \sim p_1 p_2 \]

In this section we shall investigate the occurrence of squeezing in the model-Hamiltonian
\[ H = H_1 + H_2 + V, \]  
(15)
where \( H_1 \) and \( H_2 \) are independent oscillator Hamiltonians
\[ H_i = \frac{p_i^2}{2m_i} + m_i \omega_i^2 x_i^2, \quad i = 1, 2 \]  
(16)
and \( V \) is the time-independent interaction
\[ V = \frac{k}{\sqrt{m_1 m_2}} p_1 p_2. \]  
(17)

Next, setting the coordinate transformations
\[ x_i \rightarrow \left( \frac{\hbar}{\omega_i m_i} \right)^{1/2} x_i, \]  
(18)
\[ p_i \rightarrow \left( \frac{\hbar \omega_i m_i}{k} \right)^{1/2} p_i, \]  
(19)
the Hamiltonian in Eq. (16) may be written in the form
( with \( \omega = k \sqrt{\omega_1 \omega_2} \)

\[ H = \hbar \left( \frac{1}{2} \sum_i \left( \omega_i q_i^2 + \omega_i p_i^2 \right) + \omega_p p_2 \right). \]
(19)

The Hamilton's equations of motion results ( with \( i = 1, 2; \ j \neq i \))

\[ \dot{x}_i = \omega_i p_j, \]
\[ \dot{p}_i = -\omega_i x_i, \]
(20)

leading to

\[ \ddot{x}_i = -\omega_i x_i - \omega x_j x_j. \]
(21)

We may put the foregoing equation in the matrix form

\[ \ddot{x} = -[\omega] [x], \]
(22)

where

\[ [x] = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \]
\[ [\dot{x}] = \begin{pmatrix} \dot{x}_1 \\ \dot{x}_2 \end{pmatrix}, \]
\[ [x] = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \]
(23-25)

and

\[ [\omega] = \begin{pmatrix} \omega^2_1 & \omega \omega_2 \\ \omega \omega_1 & \omega^2_2 \end{pmatrix}. \]
(26)

Now, diagonalization of the Eq. (22) is obtained in the form

\[ \ddot{X} = -[\Omega] [X], \]
(27)

where \([X] = [A]^{-1} [x] \), \([\Omega] \) is the diagonal matrix

\[ [\Omega] = \begin{pmatrix} \Omega_1^2 & 0 \\ 0 & \Omega_2^2 \end{pmatrix} \]
(28)

and \( \Omega_1^2 \) and \( \Omega_2^2 \) are the roots of the equation

\( (\Omega^2_1 - \omega^2_1)(\Omega^2_2 - \omega^2_2) - \omega \omega_1 \omega_2 = 0, \)

namely,

\[ \Omega_1^2 = \frac{\omega^2_1 + \omega^2_2}{2} + \left( \frac{\omega^2_1 - \omega^2_2}{2} + \omega_1 \omega_2 \right)^{1/2}, \]
\[ \Omega_2^2 = \frac{\omega^2_1 + \omega^2_2}{2} - \left( \frac{\omega^2_1 - \omega^2_2}{2} + \omega_1 \omega_2 \right)^{1/2}. \]
(29)

For \( \Omega_2^2 > 0 \), we must have \( \omega < \omega_1 \omega_2 \) which is equivalent to \( k^2 < 1 \).

The matrix \([A]\) is gotten from

\[ [A] = \begin{pmatrix} 1 & -\omega_2 A \\ \omega_1 A & 1 \end{pmatrix}, \]
(30)

with \( A \) given by

\[ A = \frac{\omega^2_1 - \omega^2_2}{2 \omega_1 \omega_2} + \left( \frac{\omega^2_1 - \omega^2_2}{2 \omega_1 \omega_2} \right)^2 + \frac{1}{\omega_1 \omega_2}, \]
(31)

and

\[ [A]^{-1} = \frac{1}{1 + \omega_1 \omega_2 A^2} \begin{pmatrix} 1 & \omega_2 A \\ -\omega_1 A & 1 \end{pmatrix}. \]
(32)

The substitution of Eqs. (28-32) in the Eq. (27) yields the eigenvalue equation

\[ \ddot{X}_i = -\Omega^2_i X_i, \quad i = 1, 2. \]
(33)

The application of these equations for the calculation of the variances

\[ \Delta x_i = \sqrt{x_i^2} - <x_i^2>, \]
\[ \Delta p_i = \sqrt{p_i^2} - <p_i^2>, \]

allows us to obtain, for both oscillators initially in coherent states,
where (with \( i, j = 1, 2, \ i \neq j \))

\[
\begin{align*}
\dot{f}_{ii} &= \cos \Omega t + \omega_1 \omega_2 A^2 \cos \Omega t, \\
\dot{f}_{ij} &= (\cos \Omega t - \cos \Omega t) \omega_j A,
\end{align*}
\]

and

\[
\begin{align*}
g_{ii} &= h_{ii} \omega_i + h_{ij} \omega_j, \\
g_{ij} &= h_{ii} \omega + h_{ij} \omega_j,
\end{align*}
\]

with

\[
\begin{align*}
h_{ii} &= \frac{\sin \Omega i t}{\Omega i} + \omega_1 \omega_2 A^2 \sin \Omega j t, \\
h_{ij} &= \left( \frac{\sin \Omega i t}{\Omega i} - \frac{\sin \Omega j t}{\Omega j} \right) \omega_j A.
\end{align*}
\]

Figs. (1-2) show the squeezing effect appearing in the variances \( \Delta x_1 \) and \( \Delta x_2 \) for a convenient set of parameters. Note that the effect is amplified in the variable \( x_1 \) when \( k \) increases, as shown in Fig.(2). No squeezing is observed in the variable \( p_1 \), for same values of parameters used in Fig.(2), as shown in Fig.(3) - the same occurring for variable \( p_2 \), (not shown in figures).

![Figure 1](image1.png)  
**Figure 1.** Plots of variances \( \Delta x_1^2 \) (thin line) and \( \Delta x_2^2 \) (thick line), for a set of parameters \( k = 0.5; \omega_1 = 1.0; \omega_2 = 10.0 \), showing squeezing effect in the variable \( x_1 \).

![Figure 2](image2.png)  
**Figure 2.** Same as Fig.1 for variance \( \Delta x_1^2 \), for various values of \( k \), showing the amplification of the effect when \( k \) increases.

![Figure 3](image3.png)  
**Figure 3.** Same as Fig.2 for variable \( p_1 \), showing the absence of the effect in this observable.

### IV Comments and Conclusion

We have studied the squeezing effect appearing in two coupled oscillators as shown in Figs.(1,2). When, e.g., the effect is generated in the first oscillator [see Fig.(1)] it is transferred to the second oscillator if \( \omega_1 > \omega_2 \) (not shown in figures). The present scheme explicitly involves neither nonlinearities nor time-dependent parameters, whose presences cause squeezing [1, 5, 8]. So, a raising question is: what is the origin of squeezing in our system? To answer this point, one should
remember that: (i) squeezing is essentially a nonlinear effect [1], hence some nonlinearity might be hidden somewhere in our coupled oscillators, since it is not explicitly present in the Hamiltonian given in Eq. (19); (ii) the effect also appears in “similar” systems, which results when our oscillator-oscillator system is replaced by an oscillator-atom (or field-atom) system [1-4]. In fact, it can be shown that in our case, as in [14], nonlinearities are hidden in the whole system and, when solving the Heisenberg equations of motion for the field-operators $a$ and $a^+\rangle$, we obtain from the Heisenberg equations of motion a set of coupled differential equations whose iterative solutions will show nonlinearities (e.g., quadratic terms in $a$ and $a^+$). The same occurs for the field-atom system when one employs the Jaynes-Cummings model Hamiltonian [14], being also neither nonlinear nor time-dependent. In both cases (our coupled oscillators and the coupled field-atom system of Ref. [14]), the squeezing effect originates from nonlinear couplings in these systems. In the present case, squeezing may be transferred back and forth (Fig. 2). We will show elsewhere that, if the system involves a time-dependent parameter, the effect may be transferred permanently, with no returning.
