We use the path integral approach to a two-dimensional noncommutative harmonic oscillator to derive the partition function of the system at finite temperature. It is shown that the result based on the Lagrangian formulation of the problem, coincides with the Hamiltonian derivation of the partition function.

Keywords: Noncommutative space; Partition function

I. INTRODUCTION

Recently, there has been an immense amount of challenge devoted to the subject of noncommutative space-time. Although, the idea of noncommuting space-time coordinates is an old proposal [1], the recent discoveries in string/M theories were the main source of renewed interests in the subject [2]. In particular, much work is dedicated to study the noncommutative field theories since it encodes the noncommutativity of space-time for the product of the several fields defined in the same point in the following sense:

\[ \theta \text{ with } \theta_{\mu\nu} \]

noncommutativity of space-time for the product of the several fields defined in noncommutative space [4]. In a noncommutative space-time the usual product between the coordinates and momenta (setting \( \hbar = 1 \))

\[ [\hat{x}^i, \hat{x}^j] = i\theta^{ij} \]

characterize the noncommutative version of the quantum mechanics (Latin indices stand for the spatial coordinates). An equivalent procedure to implement the star-product is to define a new set of commutating coordinates \( \hat{x}' \) via [5]

\[ \hat{x}' = \hat{x} + \frac{1}{2} \theta^{ij} \hat{p}^j \] (5)

(Through the paper summation is implied over the repeated indices). Therefore for the interaction potential \( \hat{U}(\hat{x}') \) defined in noncommutative space one gets the effective potential in usual commutative space as

\[ U(\hat{x}', \hat{p}') = U(\hat{x}' - \theta^{ij} \hat{p}^j / 2), \quad \hat{p}' = \theta^{ij} \hat{p}^j \] (6)

Path integral approach to the noncommutative quantum mechanics has revealed in series of the recent works [6]. It is demonstrated by the authors that how the noncommutativity of space could be implemented in Lagrangian formulation of the quantum mechanics. Here we aim to incorporate the effect of noncommutativity of space on the thermodynamics of a two dimensional harmonic oscillator by means of the formalism developed in [6]. So after a brief review of the Lagrangian aspect of noncommutative quantum mechanics we derive the partition function of the system by identifying the temperature as imaginary time. It is shown that the result is in accordance with one obtained via the Hamiltonian approach to the partition function.

II. LAGRANGIAN FORMULATION OF NONCOMMUTATIVE QUANTUM MECHANICS

The Hamiltonian governing the dynamics of a harmonic oscillator in noncommutative space is

\[ \hat{H} = 1/2m(\hat{p}^2 + \hat{\rho}^2) + \frac{1}{2} m \theta \omega^2 (\hat{x}_1^2 + \hat{x}_2^2) \] (7)

On implementing the transformation (5), one finds the effective Hamiltonian in usual commutative space as

\[ H = \kappa/2m(p_1^2 + p_2^2) + \frac{1}{2} m \theta \omega^2 (x_1^2 + x_2^2) + \frac{1}{2} m \theta \omega^2 (x_1 p_2 - x_2 p_1) \] (8)

with \( \kappa^2 = 1 + m^2 \omega^2 \theta^2 / 4 \) and corresponding energy spectrum as

\[ \varepsilon_{n_+, n_-} = \omega [(\sqrt{\kappa} + \sqrt{\kappa - 1}) n_+ + (\sqrt{\kappa} - \sqrt{\kappa - 1}) n_- + \sqrt{\kappa}] \] (9)
The corresponding Lagrangian can be achieved by means of the Legendre transformation $L_0(x', x^{'2}) = p^2 x'$, upon replacing for the momenta from $x^{'2} = \partial H_0/\partial p'$. Hence the Lagrangian associated with the Hamiltonian (8) will be

$$ L = \frac{m}{2\kappa} (\dot{x}_2^2 + \dot{x}_1^2) - \frac{m\omega^2}{2\kappa} (x_2^2 + x_1^2) + \frac{2m\omega^2}{2\kappa} (x_2x_1 - \dot{x}_1\dot{x}_2) $$

(10)

The above Lagrangian admits the equations of motion as differential equations of rank four. When the solutions are inserted in (10) and integrated out over the time variable $\tau$, one finds for the action

$$ S_0(x'', x', \tau) = \frac{m\omega}{2\sqrt{\kappa} \sin(\omega \sqrt{\kappa})} \left[ (x''^2 + x'^2 \cos(\omega \sqrt{\kappa})) - 2(x' \cdot x'') \cos(\omega \sqrt{\kappa} - 1) + 2(x' \times x''), \sin(\omega \sqrt{\kappa} - 1) \right] $$

(11)

with boundary condition $x'' = x(\tau)$ and $x' = x(0)$. Thus one obtains the semiclassical propagator (transition amplitude) as

$$ K_0(x'', x', 0) = \sqrt{\det(-\frac{\partial^2 S_0}{\partial x'' \partial x'})} e^{S_0} $$

(12)

$$ = \frac{m\omega}{2\pi \sqrt{\kappa} |\sin(\omega \sqrt{\kappa})|} e^{S_0} $$

where the inverse temperature parameter is defined as $\beta = i \tau$. The symbol $Tr$ stands for the functional trace which for a bi-local function $A(x, x')$ in D dimensions is defined as

$$ TrA(x, x') = \int_{-\infty}^{+\infty} d^{D}x A(x, x) $$

(14)

When the time parameter in (12) is replaced with the inverse temperature parameter $\beta = i \tau$, the semiclassical propagator (12) modifies to

$$ K_0(x'', \beta, x', 0) = \frac{m\omega}{2\pi \sqrt{\kappa} \sinh(\omega \beta \sqrt{\kappa})} e^{-S_0^F} $$

where $S_0^F(x'', x', \beta) = \frac{m\omega}{2\sqrt{\kappa} \sinh(\omega \beta \sqrt{\kappa})} \left[ (x''^2 + x'^2) \cosh(\omega \beta \sqrt{\kappa}) - 2(x' \cdot x'') \cosh(\omega \beta \sqrt{\kappa} - 1) + 2(x' \times x''), \sinh(\omega \beta \sqrt{\kappa} - 1) \right]$

(16)

The partition function $Z(\beta) = TrK_0(x'', \beta, x', 0)$ plays a vital role in thermodynamical considerations of the physical systems at finite temperature. It can be defined in terms of the propagator of system as [7]

$$ Z(\beta) = TrK_0(x'', \beta, x', 0) $$

(13)

$$ = \frac{m\omega}{2\pi \sqrt{\kappa} \sinh(\omega \beta \sqrt{\kappa})} e^{-S_0^F} $$

(18)

Therefore one is left with the partition function as

$$ Z(\beta) = \frac{m\omega}{2\pi \sqrt{\kappa} \sinh(\omega \beta \sqrt{\kappa})} e^{-S_0^F} $$

$$ = \frac{1}{2 \left[ \cosh(\omega \beta \sqrt{\kappa}) - \cosh(\omega \beta \sqrt{\kappa} - 1) \right]} $$

(17)
The above result for the partition function is derived earlier in the context of Hamiltonian formulation of the problem [8]

\[
Z(\beta) = \text{t}r e^{-\beta H_0} = \sum_{n,n'=0}^{+\infty} e^{-\beta \varepsilon_{n,n'}}
\]

(19)

\[
= \frac{1}{4 \sinh \left( \frac{\omega \beta}{2} \right) \sinh \left( \sqrt{\kappa} - \sqrt{\kappa - 1} \right)}
\]

with energy spectrum given by Eq. (9). (Note that the result of above summation derived in [8] is false since the arguments of the sinh functions must be multiplied by the factor 1/2). The free energy \( F(\beta) \) of a system at finite temperature is related to the partition function as

\[
F(\beta) = -\frac{1}{\beta} \ln Z(\beta)
\]

(20)

which at low temperature limit tends to the ground state energy of the system. In particular for the case of harmonic oscillator we have

\[
\lim_{\beta \to \infty} F(\beta) = \omega \sqrt{\kappa}
\]

(21)

which coincides with the ground state energy of the system, \( \varepsilon_{0,0} = \omega \sqrt{\kappa} \) (see Eq. (9)). In the limit \( \theta \to 0 \), the parameter \( \kappa \) tends to unity and one recovers the ground state energy of usual two-dimensional harmonic oscillator.
