Abstract: In the state of São Paulo, southeastern Brazil, the phytophysiognomy known as Cerrado takes less than 1% of its original cover. Thus, the establishment and management of protected areas are essential to save a significant sample of biodiversity of this environment in the region. The Santa Bárbara Ecological Station is one of the largest protected areas in São Paulo, and one of the few ones to cover a mosaic with most of the vegetation types of Cerrado. This article aims to increase the knowledge of avifauna in the reserve, showing new bird records and evaluating the association of species to their physiognomies. We carried out surveys from 2008 to 2013, which resulted in the record of 226 species, or 246 when in regard to Willis & Oniki’s works (1981, 2003). Twenty-two are regionally threatened, and five globally threatened. Despite showing lower species richness, grasslands stood out because of the number of species of conservation concern. Preventing the densification of woody vegetation and controlling the invasion of alien plants are important management actions for the conservation of the bird assemblages at Santa Bárbara reserve, one of the last open Cerrado remnants in São Paulo.

Keywords: conservation, protected area, management, savanna

Palavras-chave: conservação, área protegida, manejo, savanna

Introduction

In the Brazilian states of São Paulo and Paraná, Cerrado phytophysiognomies appear as open vegetation enclaves immersed in a forest matrix, establishing the southern boundary of this domain (Durigan et al. 2006). In São Paulo, where the Cerrado took nearly 14% of the area, today less than 1% of its original cover remains (Kronka et al. 2005), and only 0.5% is protected area, including ecotones with the Atlantic Forest domain (Durigan et al. 2006).

Regarded as the most biodiverse tropical Savanna, Cerrado is among the 34 areas with higher conservation priorities, also known as hotspots of biodiversity of the world (Mittermeier et al. 2004). In this context, the birds constitute the animal group best known among the 34 areas with higher conservation priorities, also known as hotspots of biodiversity of the world (Mittermeier et al. 2004). In this context, the birds constitute the animal group best known from both taxonomic and ecological viewpoints. The avifauna inventory in Cerrado remnants may contribute to select areas aimed for the creation of reserves, as well as to monitor ecological restoration actions within the already implemented ones.

There are 856 known bird species in the Cerrado domain, within which 30 (3.5%) are considered endemic (Silva & Santos...
In comprehensive analyses of Cerrado avifauna, Silva (1995a, b, 1996) excluded the Cerrado in São Paulo and Paraná, which he designated as enclaves within the Atlantic forest. Nonetheless, among the endemic species (Silva 1995b, Silva & Santos 2005), 16 (53%) of them still occur in patches located within São Paulo (Willis & Oniki 2003). For this reason, many authors believe an analysis of these bird species makes more sense when they are regarded as part of the Cerrado (Willis 2004, Motta-Júnior et al. 2008, Batalha et al. 2010, Fieker et al. 2013).

Willis & Oniki (1981) were pioneers in bird censuses in São Paulo protected areas, especially in Cerrado and semideciduous forests of interior plateaus. In their studies, they included three Cerrado areas, named ecological stations of Assis, Mogi Guaçu (formerly Fazenda Campininha), and Santa Bárbara (formerly Santa Bárbara do Rio Pardo), the latter highlighted for the occurrence of endemic and threatened species of Cerrado, as happens at the Itirapina Ecological Station (Motta-Júnior et al. 2008).

Santa Bárbara Ecological Station currently harbors up to 330 vertebrate species (São Paulo 2011, Araújo et al. 2010, 2013) and 530 vascular plants species (Meira-Neto et al. 2007, São Paulo 2011). It is one of the few protected areas to cover a mosaic with most vegetation types in Cerrado. A comparison with other Cerrado bird assemblages within São Paulo could clarify the understanding of the patterns of avian species richness and species-physiognomy relation in the Ecological Station. Published bird surveys encompass forest physiognomies of Cerrado (Telles & Dias 2010, Cavarzere et al. 2011); shrubby ones (Willis 2006); forest and shrubby ones (Motta-Júnior 1990, Dias 2000, Manica et al. 2011); forest, shrubby and grassland ones (Motta-Júnior et al. 2008), and Atlantic forest-savanna boundaries (Develey et al. 2005).

This article aims to increase knowledge of the birds at Santa Bárbara Ecological Station, showing new bird records; evaluating species richness and its relation to the local physiognomies, and examining the relevance of maintaining this reserve for the conservation of birds in the Cerrado of São Paulo.

**Material and Methods**

1. **Study area**

Santa Bárbara Ecological Station (headquarters at 22° 48’54”S and 49°14’12”W) takes an area of 2,712 ha in the county of Águas de Santa Bárbara. The altitude ranges between 600-680 m and climate is classified as Köppen’s Cwa, with warm summer and dry winter. Based on field observations and literature (Stotz et al. 1996), we classified the vegetation into three main phytophysiognomies, namely: open grass savanna, which consists of wet grassland remnants and campo cerrado; shrubby savanna (cerrado sensu stricto); and woody savanna (forest-like vegetation), formed by dense cerrado, cerradoí, woodland, semideciduous seasonal forest, riparian vegetation and marsh-like vegetation. There are also capoeiras, plots of Pinus spp. and Eucalyptus spp., anthropic fields (pastures with invasive alien grasses), and aquatic vegetation associated with streams and water reservoirs. The Management Plan for the reserve shows a map with the distribution of local physiognomies (São Paulo 2011).

The local avifauna was previously surveyed by Willis & Oniki (1981, 2003), who visited the area between 1976 and 1989, and recorded 131 bird species in 17 transect hours.

2. **Bird census**

Birds were surveyed with transect counts (Bibby et al. 1993), which consist of walking slowly at a speed of about 1 km/h on trails, firebreaks and roads, registering each individual bird contacted. We visited excerpts of all environments at Santa Bárbara Ecological Station between October 2008 and August 2013, for 380 hours of sampling effort.

Observations of birds were aided with 8 x 42 binoculars. For documentation purposes, we used professional recorders Sony PCM-D50 and Marantz PMD222, with a Sennheiser ME66/K6C Shotgun microphone, and a camera Canon SX30 IS. Sound recordings have been deposited at Xeno-Canto database (http://www.xeno-canto.org). Geographic coordinates of the main sampled areas were obtained with GPS Garmin e-Trex Summit, with geodetic system in SAD 69 Datum.

The scientific nomenclature adopted comes from the Comitê Brasileiro de Registros Ornitológicos (CBRO 2014). When defining threatened species, we followed the official list of São Paulo (Silveira et al. 2009), the Brazilian list (Silveira & Straube 2008), and the global list (IUCN red list) (BirdLife International 2014). For defining species endemic to the Cerrado, we relied on Silva & Santos (2005), Motta-Júnior et al. (2008), and Vasconcelos (2008).

Species composition was compared to other areas of Cerrado within São Paulo, namely: Botanical Garden/UNESP Reserve in Bauru (Cavarzere et al. 2011), Canchim Farm in São Carlos (Manica et al. 2010), UNESP Reserve in Corumbataí (Willis 2006), Itirapina Ecological Station (Willis 2004, Motta-Júnior et al. 2008, Fieker et al. 2013), Itirapina Experimental Station (Telles & Dias 2010), Jataí Ecological Station (Dias 2000), Cerrado Pé-de-Gigante/Vassununga State Park (Willis & Oniki 2003, Develey et al. 2005), and UFSCar, campus São Carlos (Motta-Júnior 1990) (Figure 1). Similarities (Jaccard’s index) between areas were evaluated through the UPGMA clustering analysis with Euclidean distance matrix, using the R stats package (R Development Core Team 2008).

**Results and Discussion**

We found 226 avian species, of which 128 were tape-recorded and 79 photographed, counting upon 69% of the avifauna. Along with Willis and Oniki’s transect counts, Santa Bárbara Ecological Station reaches 246 species (Table 1). The two studies had 111 species in common, reaching 45% of similarity at different times. Twenty species were found only in the 1980s, and 115 species found in this study had not been previously reported for the area, an increase of the local species list by 87%. The bird list of the ecological station can possibly be expanded with more surveys. However, the nuclear avifauna for each phytophysiognomy, i.e. the set of resident and regular migratory species (Remsen 1994), was determined. Therefore, we believe data showed here constitute a strong basis for local assemblages.

We observed 90 species in open grass savannas, 81 in shrubby savannas, and 124 in woody savannas (Figure 2). The number of exclusive species was significantly higher in the forest environments than in the savanna ones. Sick (1966) and Silva & Santos (2005) described the avifauna in Cerrado as a predominantly forest group living in a biome mainly covered by savannas, since 72% of species use forest physiognomies. Besides, several species from open formations require the
vegetation mosaic to keep their population, because they obtain resources in savanna spots and forest edges (Piratelli & Blake 2006). On the other hand, the records of threatened species were more frequent in environments with open vegetation, such as campo cerrado and wet grassland. Ignoring anthropogenic habitats and individual birds flying over, grasslands had the highest proportion of species of conservation concern (14%).

In general, Santa Bárbara assemblages correspond to 29% of the known Cerrado avifauna (Silva & Santos 2005), with six species restricted to this domain: *Melanopareia torquata* (Wied, 1831), *Antilophia galeata* (Lichtenstein, 1823), *Cyanocorax cristatellus* (Temminck, 1823), *Saltatricula atricollis* (Vieillot, 1817), *Cypsnagra hirundinacea* (Lesson, 1831), and *Neothraupis fasciata* (Lichtenstein, 1823). Seven local species are nearly threatened and twenty-two are threatened in São Paulo, within which four are in the Brazilian list and five in the global list. Among the species threatened in São Paulo, eight (38%) are in the critically endangered category, i.e. with extremely high risk of regional extinction; three were found only by Willis & Oniki (1981, 2003): *Cistocephalus platensis* (Latham, 1790), *Anthus nattereri* Sclater, 1878, and *Coryphaspiza melanotis* (Temminck, 1822).

When compared to other Cerrado sampled areas in São Paulo, Santa Bárbara is among those richer in bird
Table 1. Birds recorded at Santa Bárbara Ecological Station, São Paulo, Brazil. Types of documentation: T = tape-record; P = photograph.
Status: NT = near threatened; CR = critically endangered; EN = endangered; VU = vulnerable. SP = local list of threatened species; BR = Brazilian list; red list = global list. N = number of contacts. </table>
species, as well as in the number of endemic and threatened species (Table 1). Many other Cerrado bird assemblages in São Paulo are composed by forest species, and few are in conservation concern (Motta-Júnior 1990, Develey et al. 2005, Telles & Dias 2010, Cavarzere et al. 2011). In the Cerrado, forest habitats such as cerradão woodlands attract more forest avian species (Silva 1995b, Silva & Santos 2005), which could explain parts of the differences between studies.

On the other hand, Santa Bárbara and Itirapina Ecological Stations were more similar regarding the different types of avifauna, differing from geographically closer areas (Figure 3). It has been suggested that closer specific composition in both areas is due to similarities in the mosaic of grassland and savanna physiognomies and their surroundings (Willis 2004, Motta-Júnior et al. 2008). Differences in species composition between them probably reflect the proportions of occupation by physiognomies on each. Santa Bárbara has a greater extension of arboreal formations, which takes nearly 20% of its surface while in Itirapina, grasslands cover 40% of the area (São Paulo 2006, 2011). Apart from that some absences in the Santa Bárbara assemblage are due to the distribution of certain species in the state, for instance, Clibanornis rectirostris (Wied, 1831) and Myiothlypis leucophrys (Pelzeln, 1868) from Itirapina riparian vegetation, which are lacking on the left bank of Tietê river (Willis & Oniki 2003).

Grassland avifaunas in both Santa Bárbara and Itirapina are highlighted for the number of threatened species (Motta-Júnior et al. 2008). Within these reserves, grasslands have lost their areas due to colonization by pine Pinus elliottii Engelm as well as by vegetation densification, with more intensity at Santa Bárbara where previously it was practiced extensive livestock. To make cattle farming possible, people used to set fire in the local vegetation, favoring the grasslands and preventing an increasing in tree density. With the suppression of these activities, open-habitats tend to be restricted to areas where the soil suffers water saturation, at least seasonally (São Paulo 2011). Moreover, avoiding fire, which leads vegetation densification, may eliminate bird habitats in the medium and long terms, since several species are adapted to the fire dynamic in the Cerrado (Parker III & Willis 1997). In turn, the loss of grassland birds will have an impact on local ecological processes in both reserves, since this assemblage is functionally complementary to the forest and savanna environments (Batalha et al. 2010).

Scientific evidence about management implications on fauna, such as avoiding fires aiming to improve the effectiveness of protected areas, is still limited (Geldmann et al. 2013). The Santa Bárbara Ecological Station Management Plan was recently completed (São Paulo 2011). Its main goal is to recover local physiognomies to the proportions observed in 2011. To reach this goal, some priority researches were listed, such as the role of controlled fires and herbivory in order to maintain the mosaic of vegetation, and the controlling and eradication of invasive exotic plant species (São Paulo 2011). These researches

Figure 3. UPGMA clustering of Cerrado areas with bird assemblages sampled within São Paulo, with leaves hang according to the Euclidean distances from each other.
must evaluate the natural occurrence of fire, its frequency, and which areas need to be managed annually to maintain the percentage representation of physiognomies. Results obtained in other Cerrado regions may not necessarily be generalized, with case studies and gathering of researchers from different knowledge areas important to carry out a comprehensive evaluation (França et al. 2007).

Thus, avifauna monitoring may contribute to evaluate the effectiveness of management actions at Santa Bárbara Ecological Station, especially when regarding noteworthy records.

1. Noteworthy records

**Greater Rhea Rheas americana (critically endangered, SP).** Species globally nearly threatened and heavily hunted in the region in recent decades, as well as suffering from poisoning by use of herbicides and frequent burning of vegetation. In São Paulo, the species has been seen only on the border with Mato Grosso do Sul state, and at Itirapina Ecological Station (Motta-Júnior et al. 2008). At Jataí Ecological Station, it was already common in the 1960s, but it is now disappeared (Dias 2000). In our study, we recorded Greater Rhea solely by tracks on October 21, 2009 (22°49'30''S, 49°14'51''W) and a photograph taken by camera trap, installed by mastozoologists on 09/01/2008. Nowadays, the local species occurrence has been reported only to a disturbed Cerrado area at Thermas de Santa Bárbara, a settlement surrounding the reserve, what warrant additional surveys covering both their inner and outer areas.

**Rufous-faced Crane Lophotis xenopterus (critically endangered, SP; vulnerable, Red list).** Some duets of this secretive crake were heard in contact areas between wet grasslands and riparian vegetation. A recording was obtained on October 23, 2009 at coordinates 22°48'54''S and 49°10'41''W. This is a poorly known species deemed to be threatened both in the state and in international lists. Its occurrence in São Paulo until then was based on a single specimen, found dead on a railway line in the town of Itirapina (Willis 2004, Vasconcelos et al. 2006). Despite lacking records, it can be more widespread than we think. Its trilling call’s similarity with congeners and sympatric species globally nearly threatened and heavily hunted in the region in recent decades, as well as suffering from poisoning by use of herbicides and frequent burning of vegetation. In São Paulo, the species has been seen only on the border with Mato Grosso do Sul state, and at Itirapina Ecological Station (Motta-Júnior et al. 2008). At Jataí Ecological Station, it was already common in the 1960s, but it is now disappeared (Dias 2000). In our study, we recorded Greater Rhea solely by tracks on October 21, 2009 (22°49'30''S, 49°14'51''W) and a photograph taken by camera trap, installed by mastozoologists on 09/01/2008. Nowadays, the local species occurrence has been reported only to a disturbed Cerrado area at Thermas de Santa Bárbara, a settlement surrounding the reserve, what warrant additional surveys covering both their inner and outer areas.

**Ocellated Crane Micropogia schomburgkii (critically endangered, SP).** Heard in patches of campo cerrado, sometimes over wet grasslands. This rail responds well to playback techniques, even at a distance. We noticed that this species approaches when closer to the sound source, walking carefully and silently. Nonetheless, this behavior probably does not prevent its detection, as the species has been recorded increasingly in other parts of Brazil by ornithologists who have knowledge of its vocalization (Vasconcelos et al. 2006, Lopes et al. 2009). In São Paulo, the species is threatened by conversion of grasslands to monoculture plantations, being detected only once in a narrow range of Cerrado at Lençóis Paulista (Marcondes & del Rio 2012).

**Sharp-tailed Tyrant Calicivora caudacuta (critically endangered, SP; vulnerable, BR, Red list).** Species present in the few dry natural grasslands and more open moist fields with tall grasses that remain in the ecological station. Known for nesting in bushes of ironweed Vernonia (Asteraceae; del Hoyo et al. 2004), C. caudacuta can rely on seven herbaceous species of this genus in campos cerrados of Santa Bárbara (São Paulo 2011). Due to current loss of habitat outside nature reserves in southeastern Brazil, it has a strong tendency to remain confined in the few protected dry grasslands such as Santa Bárbara Ec. St., free of charge by agricultural conversion.

**Cock-tailed Tyrant Alectrurus tricolor (critically endangered, SP; vulnerable, BR, Red list).** This species currently shows irregular distribution, largely due to the rarity of undisturbed open-habitats, especially tall grasses. In the Cerrado, these environments have been quickly converted in agricultural areas. In São Paulo, this species has not been detected in other places, except at Itirapina Ecological Station (Motta-Júnior et al. 2008). When breeding, males display nuptial conspicuous behaviors such as flights up to 4 m in height followed by freefalls to the ground, and vertical movements of the long tail. This behavior was observed near to a female on October 21, 2008 (22°47'08''S, 49°14'24''W) at a site recovering from burning.

**Sedge Wren Cistothorus platensis (critically endangered, SP).** Open-habitat species with a large vocal repertoire, usually forages low down in vegetation looking for insects. Inhabitants of campos, seasonally wet grasslands and freshwater marshes, it has declined due to habitat loss from changes in land use, and converting natural grasslands to forestry and pastures. In Santa Bárbara, this bird was once relative abundant in the 70s and 80s with a record of 27 individuals in 17 transect hours (Willis & Oniki 1981). It has not been recorded there recently and even using sound emissions by playback techniques, intensive searches in habitats with potential occurrences were not successful in finding the species, suggesting a possible local extinction (A.S. Lucindo & M.M. Dias, unpublished data). It is necessary a detailed search for isolated population of the
species at surroundings, in order to develop management actions.

**Ochre-breasted Pipit Anthus nattereri** (critically endangered, SP; vulnerable, BR, Red list). Grassland species are known for preferring burnt areas (not over-frequent burnings) and lightly grazed grasslands (Parker III & Willis 1997). Although recorded in Itirapina in the past, the species has not been sighted since 2000, even during breeding season (Willis 2004, Motta-Júnior et al. 2008), suggesting a possible local extinction. In Santa Bárbara, the species has not been found since Willis & Oniki’s studies, even using playback sounds from elsewhere (A.S. Lucindo & M.M. Dias, unpublished data). It makes even more serious the situation of the species on site. As it is a restricted species regarding the environment occupied, it may have disappeared due to conversion of grasslands into *Pinus* plantations and vegetation densification (Silveira et al. 2009). Further studies are needed to clarify its actual condition locally.

**White-rumped Tanager Cypsnagra hirundinacea** (endangered, SP). Although considered rare in São Paulo, the species is frequently observed in *campos cerrados* in the ecological station, forming monospecific flocks from two to three individuals. It is commonly seen foraging for insects in the tree and bush stratum above 1.5m. It is highly territorial, since actively responds to audio playback, vocalizing and flying over the sound source in searching for the supposed intruder. In São Paulo, it is threatened due to disturbance and destruction of their habitats (Silveira et al. 2009).

**White-banded Tanager Neothraupis fasciata** (endangered, SP). Species usually observed in groups of two or more individuals in the *campo cerrado* and cerrado *sensu stricto*, sometimes feeding on the ground. We found this species joining mixed flocks with *S. atricollis*. Their diet includes insects, seeds and fruits. In the ecological station, the bird actively feeds on *Aegithalos concinnus* (Lamiaceae) when bearing fruiting. The main threat to its existence is the conversion of natural areas into pasture and farmland (Silveira et al. 2009).

**Plumbeous Seedeeater Sporophila plumbea** (endangered, SP). Coveted for cagebird trade, this short-distance migrant species also suffers from habitat loss, which must be addressed through the conservation of natural grasslands. In Jataí, it was frequently seen in the 60s, but has not been observed recently (Dias 2000). In Cerrado Pê-de-Gigante, it was usually observed in the 90s (Develey et al. 2005). For now, Santa Bárbara along with Itirapina emerge as priority conservation areas for *Sporophila* seedeaters in general, since they still rely on Cerrado formations and specific grassland environments. However, both invasive grasses and vegetation densification due to fire protection have led to a gradual modification of their preferential habitat.

**Pearly-bellied Seedeeater Sporophila pileata** (vulnerable, SP). Originally considered as a subspecies of *S. bouvreuil* (Copper Seedeeater), this taxon was recently recognized as a full species (Machado & Silveira 2010). Some couples have been spotted in *campo cerrado* when foraging in mixed flocks with *S. plumbea*, which can indicate the use of the region as a stopover on their migratory routes.

**Black-masked Finch Coryphasipa melanotis** (critically endangered, SP; vulnerable, BR, Red list). Restricted bird to grassland environments, it usually lives on the ground, rising in grasses with emerging stalk during its breeding season. The Black-masked Finch has high research and conservation priority, because it is a rare and declining species (Sotz et al. 1996, Silveira & Straube 2008). Recently, some efforts to find it using playbacks were not successful at Santa Bárbara grasslands, suggesting a possible local extinction (A.S. Lucindo & M.M. Dias, unpublished data). However, it is worth considering that the species was detected by Motta-Júnior et al. (2008), and a few years thereafter it was thought to be extinct in Itirapina (Willis 2004). Therefore, new searches covering the surroundings are needed to find some isolated population, and develop management actions.

### 2. Concluding remarks

To recognize the species at Santa Bárbara Ecological Station is the first step towards preparing an effective strategy to conserve the local avifauna. Key approaches to improve knowledge of this bird assemblage include analyses of habitat use via BARCI designs (Before-After Reference Control-Impact), and population size estimates for species of conservation concern (e.g. Kanegae 2011, Kanegae et al. 2012a, 2012b). Conservation of the grassland and savanna biota at Santa Bárbara Ecological Station in the medium and long terms is a challenge that must be faced with management grounded on scientific research. Knowledge of birds at this reserve will allow us to use local avifauna as an indicator of the effectiveness of actions deployed.

### Acknowledgments

The authors thank the Instituto Florestal do Estado de São Paulo and its staff for fieldwork support at Santa Bárbara Ecological Station; Marco Port Carvalho, for kindly providing the photograph of the Greater Rhea; and the anonymous reviewers, for criticism and suggestions. A.S. Lucindo is a PhD candidate, and receives a doctoral scholarship from CAPES.
