Depressive symptoms in the elderly and its relationship with chronic pain, chronic diseases, sleep quality and physical activity level

Sintomas depressivos em idosos e sua relação com dor crônica, doenças crônicas, qualidade do sono e nível de atividade física

Marcia Regina da Silva¹, Fátima Ferretti², Samira da Silva Pinto³, Odanor Ferretti Tombini Filho³

ABSTRACT

BACKGROUND AND OBJECTIVES: Depressive symptoms are often experienced by the elderly, being a public health problem. The objective of this study was to verify the relation between depressive symptoms and the presence and intensity of chronic pain with sleep quality and physical activity level.

METHODS: Research with 385 aged residents in a municipality of Santa Catarina. The Morais adapted questionnaire, the numerical visual pain scale, and the International Physical Activity Questionnaire were used to assess the level and volume of physical activity, the Pittsburgh Sleep Quality Index, and the Geriatric Depression Scale. Data analysis by the Mann-Whitney U test, Chi-square (X²) and Spearman’s correlation.

RESULTS: Of the 385 aged evaluated, 30.6% had depressive symptoms. Older people who had depressive symptoms complained more of pain, poor sleep quality and had less physical activity (p=0.001). The X² values between chronic pain, sleep quality and physical activity level with presence and absence of depression symptoms were 25.078, 27.707 and 9.009, respectively (p<0.05), and the correlation between depressive symptoms and sleep quality was 0.423 (p<0.05).

CONCLUSION: Elderly people with depressive symptoms had a higher intensity of pain, worse quality of sleep and lower intensity of physical activity. There was an association between the presence of chronic pain, level of physical activity and quality of sleep with depression symptoms and moderate correlation between depression symptoms and sleep quality.

Keywords: Chronic pain, Depressive symptoms, Elderly, Exercise, Sleep disorders.

INTRODUCTION

The aging of the population is a worldwide phenomenon. Demographers forecast that in the year 2020 there shall be some 1.2 billion senior citizens in the world, including 34 million Brazilians aged over 60. A series of factors, including better control of chronic diseases, the improvement of the quality of life (QoL), the reduction of birth and fecundity rates, among others, have together helped to raise the life expectancy of the population¹. Brazil can now be considered “a young country with grey hair.” Every year, 650 new senior citizens enter the Brazilian population, most of which with some kind of chronic disease and some with limitations of movement. In less than 40 years, Brazil shall move
Depression is one of the most common chronic diseases among senior citizens, now being one of the world’s main public health problems, affecting some 350 million people throughout the world. Depression is also a major cause of disability that triggers other diseases. Due to its importance, and to the increase in its prevalence, depression has been chosen as the campaign theme for World Health Day in 2017, by the World Health Organization (WHO)⁴. A systematic review showed that the prevalence of depression is found in 7.7% of senior citizens seeking primary health care, 10.4% of those living in communities, and 14.4% of those who are in a hospital environment⁵. Also, depression is more common among senior citizens who have incapacitating physical problems⁶. According to the research carried out by Wannmacher⁷, these symptoms reduce the QoL and increase mortality. The WHO⁸ estimates that in 2020, ischaemic heart disease and depression will be the two main causes of death and disability.

Depressive symptoms (DS) in senior citizens are related to a greater difficulty in the treatment of comorbidities, worse prognosis, and also a worse QoL, and they should be thoroughly investigated to provide early treatment and improve the general well-being of this population, already frail by the several diseases that affect this segment of the population. Therefore, it becomes relevant to identify the DS and relate them to other variables, so that one may intervene with preventive measures, thereby preventing the evolution of this clinical situation to full depression.

In face of this scenario, the objective of this study was to check the relationship between DS in senior citizens, and the presence and intensity of chronic pain with the quality of sleep and level of physical activity (LPA). Also, if there is an association between chronic pain, quality of sleep, and LPA with DS, and the connection between DS and the number of chronic illnesses, the sleep quality index, the volume of physical activity, and pain intensity.

**METHODS**

This study is quantitative, transversal and populational in nature and was conducted in a city of the state of Santa Catarina, from June to August 2016. This study had the participation of senior citizens of both genders, resident in the urban area of that city.

The state of Santa Catarina has a dynamic that is reflected in its high growth and literacy rates, high employment, and high per capita income, significantly higher than the national mean, thereby ensuring growth and literacy rates, high employment, and high per capita income. The state of Santa Catarina has a dynamic that is reflected in its high growth and literacy rates, high employment, and high per capita income, significantly higher than the national mean, thereby ensuring growth and literacy rates, high employment, and high per capita income. Also, a worse QoL, and they should be thoroughly investigated to provide early treatment and improve the general well-being of this population, already frail by the several diseases that affect this segment of the population. Therefore, it becomes relevant to identify the DS and relate them to other variables, so that one may intervene with preventive measures, thereby preventing the evolution of this clinical situation to full depression.

In face of this scenario, the objective of this study was to check the relationship between DS in senior citizens, and the presence and intensity of chronic pain with the quality of sleep and level of physical activity (LPA). Also, if there is an association between chronic pain, quality of sleep, and LPA with DS, and the connection between DS and the number of chronic illnesses, the sleep quality index, the volume of physical activity, and pain intensity.

Also, if there is an association between chronic pain, quality of sleep, and LPA with DS, and the connection between DS and the number of chronic illnesses, the sleep quality index, the volume of physical activity, and pain intensity.
Next, the MEEM was applied and used as an inclusion criterion, as it sorts out the subjects based on the preservation of cognition of the senior citizens. The interpretation of the MEEM was based on the following scores: 17 points for illiterates or people who have less than four years of formal education; 24 points for people with four or more years of education. The senior citizens who reached these cut-off points were kept in the study, while the others were excluded, on the grounds of not having a satisfactory cognition level.

Afterward, the questionnaire for senior citizens general data – adapted from Moraes, was applied. This instrument consists of personal information and questions about the presence of pain and self-reported chronic diseases.

Then, the VNS was applied, which helps to measure the intensity of pain experienced by the patient, on a scale from zero to 10. The senior citizen classified his/her pain by intensity where from zero to three corresponds to “mild pain,” four to seven, “moderate pain,” and eight or higher, “severe pain.”

To assess the physical activity, we applied the IPAQ, short version, which the main objective is to estimate the energy consumed when performing a physical activity, whether moderate or vigorous, but always taking into account the daily tasks, leisure, and work, among others. Barbosa et al. showed that the IPAQ assesses different aspects, including work, household chores, and leisure, also estimating the time taken for the execution of these activities, characterizing the level of activity (active or sedentary).

According to the result obtained, the IPAQ was divided and defined based on different categories as follows:

- Insufficiently active (A and B): people who take up to 150 minutes of physical exercise activities per week;
- Active (Active A-B and very active): people who take more than 150 minutes of physical exercise per week.

The next step was the application of the PSQI, a questionnaire designed to assess the quality of sleep in the most recent month. This questionnaire has 19 questions, grouped in seven components, with weights distributed on a scale from zero to three. The scores of these components are added to produce a global score, varying from zero to 21. Scores from zero to four indicate good sleep quality, while scores from five to ten show poor sleep quality and scores over ten show evidence of sleep disorders.

Finally, to check the presence of depression symptoms, we used the GDS short version, with 15 questions. The final score can reach a maximum of 15 points, and scores where the sum is 4 points or less represent lack of DS, while five or more points suggest the presence of DS.

The Project that gave rise to this study was analyzed and accepted by the Human Research Ethics Committee, of the Higher Education Institution, with opinion No. 2.047.037. This study assured that the ethical principles are in compliance with the Ruling 466/12 of the National Health Council.

### Statistical Analysis

For data analysis, we used an Excel spreadsheet to store the data. The analysis was performed by the SPSS statistical software, version 20.0. Initially, we run the descriptive statistics, and the quantitative variables were analyzed by measurements of dispersion and central tendency (mean and standard deviation). The analysis of the qualitative variables was based on relative and absolute frequency. The normality of data such as pain, sleep, physical activity, and DS was checked based on the Kolmogorov-Smirnov test. Since it did not show a normal distribution, the comparison of medians and the interquartile range was analyzed using the U Mann-Whitney test in senior citizens with presence and absence of DS, as well as in the groups with and without chronic pain. To check the association between chronic pain, sleep quality and level of physical activity (LPA) with presence and absence of DS, the Chi-Square test ($\chi^2$) was performed. The correlation between variables was obtained by the Spearman correlation test, using a level of significance of $p<0.05$.

### RESULTS

Of the 385 senior citizens interviewed, 259 were women. The mean age observed was $71.12\pm7.46$ years. In all, 118 patients with DS were identified (30.6%), and it was also observed that among all senior citizens with DS, most were women (86 senior citizens, 72.9%).

Regarding chronic pain, 224 senior citizens reported the presence of pain; 74.5% were women. When we looked at the rating of pain with the VNS, we obtained a mean of $3.46\pm3.49$. The greatest frequency was concentrated in the case of moderate pain (with scores between four and seven points on the pain scale), or 28.1% of patients. This was followed by intense pain (a score between eight and ten) and finally mild pain (scores between one and three). In the case of female senior citizens, there was a prevalence of intense pain, which was recorded in 82.4% of the group.

We also observed 331 patients with chronic pain (86%). Regarding the number of diseases, the senior citizens reported between 1 and 6 chronic diseases. Most of the senior citizens had up to 3 self-reported diseases (79%) (Table 1).

VNS = visual numeric scale for pain; PSQI = Pittsburgh Sleep Quality Questionnaire; GDS = Geriatric Depression Scale.
Comparing the medians of variables such as pain, sleep quality, and volume of physical activity among senior citizens with the presence or absence of DS, the results show that senior citizens with DS had more complaints of pain, poorer sleep quality, and also less practice of physical exercise (p=0.001), as shown in table 2 below.

Table 2 shows the data regarding the medians of sleep quality, the volume of physical activity and DS in senior citizens with and without chronic pain, showing results that are statistically significant between the groups.

Table 4 shows chronic pain, sleep quality, and level of physical activity among senior citizens with and without DS. The results suggest a statistically significant relationship between the presence of DS and the presence of chronic pain, worse sleep quality, and a lower level of physical activity.

One of the main results of this study was the relationship between DS and the presence and intensity of chronic pain. In addition, the senior citizens who reported chronic pain were 3.36 times as likely to have DS, as shown by the X² test. A study with 172 senior citizens at a Basic Health Centre in the city of Londrina, State of Paraná, Brazil showed that 62.21% of these patients had chronic pain, and 56.1% had DS¹⁹. According to a study conducted by Pinheiro et al., there is a high prevalence of DS and anxiety in patients with chronic pain, as also a significant connection between these psychiatric symptoms and some types and intensity of pain. Melancholy intensifies a painful experience or reduces the pain threshold²¹,²². A cycle is therefore established, in which one disorder makes the other worse. A dejected patient is less active and restricts his/her social coexistence, which could intensify the situations of pain and worsen the DS, and so on in an endless succession²³.

The results of the present study have also shown that senior citizens with DS have shown a significantly higher intensity of pain and higher GDS scores in the presence of chronic pain. One study that assessed the relationship between pain and depression, in a population of senior citizens, based on information regarding senior citizens who received home services in 11 European countries between 2001 and 2003, showed that of the total sample, 2380 people had pain (59.9% of the sample). Depression was diagnosed in 11.3% of the 1596 participants who reported no pain and in 19.5% of the participants who had pain (p<0.001). Comparing by gender, we see that women with pain were much more likely to show DS. Among women, the association between pain and DS became gradually more significant, with increases in pain intensity, pain frequency, and the number of painful sites²⁴.

Many neurotransmitters that act upon the central nervous system (CNS) are also related to the suppression of pain, including serotonin and NADr²⁵, which are reduced in patients with DS and chronic pain²⁶. A population-based prospective cohort study, with four follow-up measurements over 13 years, conducted in Amsterdam with 1528 interviewees (mean age of 67.9±8.1 years), seeking to investigate the effect of age and of the aging process on the association between pain and DS, showed that pain and DS were associated throughout the 13 years of monitoring. The somatic and...
psychological characteristics could explain 40% of the covariance between pain and DS, over time. When we deal with people who suffer from pain and depression, the interventions used should be similar for all senior citizens, covering somatic and psychological factors, regardless of the interviewee’s age or degree of frailness. In this direction, interventions that could make senior citizens aware of the need for healthy eating habits, together with regular physical exercise, activities in the open air, and getting some sun at appropriate times, favour an increase in the presence of serotonin and could reduce this cycle: more DS, more chronic pain, and vice versa. The study has shown a weak correlation between the number of diseases, the presence of DS, and the frequency of self-reported chronic diseases. According to the study by Duarte and Rego, of the 1,120 senior citizens who attended a geriatric outpatient center in the city of Salvador, State of Bahia, 91% had between 1 and 5 chronic diseases, and 23.4% of all the people assessed were diagnosed as having DS, this situation was more common among women. Another fact observed was that there was a positive association between the number of comorbidities and situations of depression, when there were more than 3 chronic diseases.

The studies by Teng, Humes and Demetrio and Martínez et al. reached the conclusion that DS is related to many diseases, and that the presence of DS helps to worsen the symptoms of chronic diseases, the QoL indexes, treatment compliance, and also brings greater morbimortality among patients. A cross-sectional study with adults aged between 20 and 59, in the city of Florianópolis, showed an occurrence of 16.2% of depressive patients, this being more common among women and older people. This study also showed that the occurrence of DS was higher among those subjects with a higher number of chronic diseases. Another result showed by this study was the moderate connection between DS and sleep quality, and also that senior citizens with DS obtained significantly worse scores than those without DS. According to the Manual for Diagnosis and Statistics of Mental Disorders, 5th version, changes in sleep are just one of the symptoms that are part of the criteria to identify depression (DSM-V-tr, 2014). A significant number of depressed patients complain about a general deterioration of their sleep, both in qualitative and quantitative terms. This non-reparative sleep leads to irritability, difficulty to concentrate, and daytime fatigue. Moreover, changes in sleep patterns could also be an indicator of the likelihood to develop DS. A study described that, among the factors that cause sleep disorders, were the presence of pain (33.1%) and indeed, pain interferes with sleep quality among senior citizens, but, even though it occurs mostly in aged people, it is not in itself a cause of sleep disorders – these alterations are normally associated to other comorbidities and worse QoL scores among senior citizens, as well as DS. When the senior citizen’s sleep pattern is interrupted, it can reduce the motivation and willingness to participate in social and recreational activities, thereby hampering the performance of daily activities and creating situations of dependence and reduction of well-being.

Thus, health professionals should intervene with actions to promote health, actions that reduce or prevent sleep-related problems. Among the strategies, we could highlight physical exercises, relaxation techniques, integrative and complementary practices, conversation groups, and therapy and support groups.

When we looked at the association between the LPA and the degree of DS, we observed that the group of insufficiently active senior citizens had a higher prevalence of DS (49.2%). In the case of senior citizens without DS, 58.1% are active and very active. When comparing the volume of physical activity, senior citizens with DS showed significantly lower volumes of physical exercise, compared to those without DS.

One review that evaluated the benefits of physical activity in depressed patients, conducted by Guimarães and Caldas found 15 studies in seven different countries (the U.S., the Netherlands, Brazil, England, Japan, Colombia, and Finland), reaching the conclusion that physical activity reduces DS among senior citizens. Among the most accepted explanations for the benefits that physical exercises bring to the treatment of DS are the increase in the release of catecholamines such as serotonin, noradrenaline and dopamine and also endorphins, that promote a general feeling of well-being, relieving DS and producing a feeling of content and of willingness to do things.

Encouraging a healthy lifestyle, with the regular practice of physical exercises, reduces the risk of development of diseases in this population. The promotion of physical activities together with better living conditions could, indeed, have a positive impact on the improvement of the QoL in the general population. Within this context, the health care team needs to plan actions, not only to treat the clinical conditions that occur in this phase of life but also to implement interventions to prevent, maintain and promote the physical and psychological health of senior citizens so that they can enjoy life with longevity.

CONCLUSION

Based on the results obtained in this study, there is a connection between DS and the presence and intensity of pain, sleep quality, and the LPA. It was also observed that senior citizens with chronic pain showed worse scores for sleep quality, physical activities, and increased DS. There was also a relationship between the presence of chronic pain, low LPA and poor sleep quality among senior citizens with DS.
