Starter cultures used in probiotic dairy product preparation
and popular probiotic dairy drinks
Oktay YERLIKAYA*  

Abstract
Dairy products that contain probiotic bacteria are those that are produced with various fermentation methods, especially lactic acid fermentation, by using starter cultures and those that have various textures and aromas. Fermented dairy products are popular due to their differences in taste and their favourable physiological effects. Today, fermented dairy beverages in general are produced locally by using traditional methods. Recently, due to the increased demand for natural nutrients and probiotic products, fermented dairy beverages have reached a different position and are considered to have an important impact on human health and nutrition. In this article, probiotic bacteria and functional dairy products that are produced by using probiotic bacteria are discussed.

Keywords: probiotics; fermented dairy products; lactic acid bacteria; dairy drinks.

1 Introduction
Fermented dairy products are products that can be produced via fermentation of lactose by microorganisms especially by lactic acid bacteria. When examining worldwide, various dairy products which are different in name but similar in content can be found and those products are an important part of human diet (Tamime & Marshall, 1997; Moayedian et al., 1999; Tamime & Robinson, 1999; Nilsson et al., 2006; Hugenholz, 2013). Fermented dairy products in question are usually produced by using lactic acid bacteria and yeasts (Ozer & Kirmaci, 2010). Fermented dairy products that are produced with different fermentation types are shown in Table 1.

Probiotics are defined as living microorganisms, which when ingested in sufficient amounts, beneficially influence the health of the host by improving the composition of intestinal microflora. In addition to improving gut health, probiotics may play a beneficial role in several medical conditions, including lactose intolerance, cancer, allergies, hepatic disease, Helicobacter pylori infections, urinary tract infections, hyperlipidemia and assimilation of cholesterol (Ejtahed et al., 2011). Probiotic microorganisms that are known to be beneficial to human health can be ingested through fermented dairy products, enrichment of various foods with these bacteria and consumption of pharmaceutical products that are obtained by using viable cells (lyophiled preparations and tablets). Probiotics are defined as viable microorganisms which can be consumed separately or with foods, which assist dietary and microbial balance by regulating the mucosal and systemical immunity and beneficially affect the consumer’s health. A great variety of dairy products contain probiotic bacteria (Ziemer & Gibson, 1998; Moayedian et al., 1999; Salminen et al., 1999; Gibson & Fuller, 2000; Granato et al., 2010; Guldas & Irkin, 2010; Kanmani et al., 2013; Lollo et al., 2013).

Probiotic foods enhance health after consumption and contains microorganisms which are viable, specific and effective on main systems of nutritional physiology. In Japan, probiotics are consumed as frozen culture tablets whilst in Europe, due to the bias against medication, probiotics are only consumed through the inclusion of probiotics to foods (Vaughan & Mollet, 1999; Shah, 2001; Soccoll et al., 2010).

Fermented milks have long been used as the main vehicles for probiotic strains. Less frequently, cheeses have been used for incorporation of probiotic microorganisms, but they may offer a number of advantages compared with fermented milks (Gomes et al., 2011; Minervini et al., 2012). Cheese has higher pH, more solid consistency, and relatively higher fat content compared with fermented milks such as yoghurt (Karimi et al., 2012).

2 Selecting probiotic strains for probiotic dairy products
Probiotic dairy products have favourable effects on human health such as, reducing lactose intolerance, prevention of diarrhea and constipation, increase in the effectiveness against Helicobacter pylori infection, preservation of oral health, partial prevention of cancer, cholesterol lowering, enhancement of mineral absorption. Along with their extensive effects on human health, they have the ability to form low molecular weight components such as conjugated linoleic acid (CLA), gamma aminobutyric acid (GABA) and bacteriocin (Gobbetti et al., 2010; Šušković et al., 2010; Divya et al., 2012; Kanmani et al., 2013).

Several factors must be considered when using probiotic bacteria in fermented products like yoghurt. Primarily, the probiotics must be viable and present in high count at time of consumption to achieve the desired benefits. Thus, a probiotic dairy product should contain at least 6–7 Log cfu.g⁻¹ of viable probiotic bacteria at the time of consumption and, should be
Popular probiotic dairy drinks

Selection criteria in regard to the selection of the appropriate probiotic bacteria and strains are: a) The respective bacteria have to be reported in the literature, b) There should be concrete proofs of their assistance to health c) They have to be able to colonise in gastrointestinal tract and have a regulatory role in microbial balance in that area, d) In order to sustain their viability in gastrointestinal conditions, they have to be resistant to low pH values and bile salt e) They have to possess natural antibiotic effect, in order to prevent pathogen growth with their antimicrobial activity f) They have to be safe to consume and show no antibiotic resistance g) They have to be suitable for commercialisation (Radulović et al., 2010; Soccol et al., 2010; Figueroa-González et al., 2011; Giraffa, 2012; Sharma et al., 2014). The possible interactions among the probiotic strains selected to manufacture dairy product should be taken into account to select the best combination(s) and to optimize their technological performance in the process and their survival in the products during cold storage (Saccaro et al., 2009: Casarotti et al., 2014).

Exposure to oxygen may induce a lack of functionality of probiotic dairy products because the anaerobic metabolism of probiotic bacteria compromises during storage the maintenance of their viability to provide benefits to consumer health. The exposure to oxygen along the refrigerated storage constitutes a technological challenge with respect to the maintenance of the probiotic dairy products, once a great part of the probiotic microorganisms grow in anaerobic systems.

### Table 1. Fermented dairy products, countries and microorganisms based on fermentation types (Yilmaz, 2006).

Glucose oxidase which is an enzyme produced by fungi such as Aspergillus and Penicillium can constitute a potential alternative to increase the survival of probiotic bacteria in fermented milks (Cruz et al., 2010, 2012).

**3 Popular probiotic microorganisms used in production of functional dairy products**

Probiotic microorganisms are isolated from human gastrointestinal system. Lactobacillus and Bifidobacterium species are widely known. E. faecium, E. faecalis, S. thermophilus, L. lactis subsp. lactis, Leuconostoc mesenteroides, Propionibacterium freudenreichii, Pedicoccus acidilactici, Sporolactobacillus inulinus, E. coli, bacteria such as some Bacillus species, other lactic acid bacteria species, yeast such as Saccharomyces cerevisiae and Saccharomyces boulardii are commonly used as probiotics. (Foulquié Moreno et al., 2006; Parvez et al., 2006; Granato et al., 2010; Cutting, 2011; Naggal et al., 2012). Interest for probiotics has arisen in recent years especially in relation to the addition of Bifidobacterium, Lactobacillus acidophilus, Lactobacillus rhamnosus, Lactobacillus casei, Lactobacillus reuteri to the fermented dairy products such as yoghurt (Guldas & Irkin, 2010). Microorganisms that are being used to produce probiotic dairy products and that make preparations are shown in Table 2.

**Lactobacillus acidophilus** and **Bifidobacterium animalis** subsp. lactis are the lactic acid bacteria that are most frequently used as probiotics. These bacteria grow slowly in milk because they lack essential proteolytic activity and for this reason they are usually combined with Streptococcus thermophilus (Casarotti et al., 2014). Probiotic dairy products should have desired sensorial properties besides the probiotic properties. In order to achieve optimal sensorial properties, mixture of different bacteria can be used. Lactobacillus delbrueckii sps. bulgaricus are widely used in those combinations due to their acid formation and production of aroma substances such as acetaldehyde. One of the optimal combination of those probiotic bacteria is a culture called ABT which has a combination of L. acidophilus, Bifidobacterium lactis and S. thermophilus. ABY cultures have the the same combination with ABT cultures with an addition of L. bulgaricus and these cultures can be used to produce yoghurt (Parvez et al., 2006; Granato et al., 2010; Casarotti et al., 2014).

**4 Lactobacillus acidophilus**

L. acidophilus is a gram positive, anaerobic or facultative anaerobic, nonmotile, catalase (-), rod-shaped bacteria. It is a homofermentative bacteria which has an optimum growth temperature of 35-38 °C and optimum pH interval of 5.5-6 (Tamime & Marshall, 1997; Ozbas, 2004). It doesn't produce ammonia from arginine but ferments amygdalin, cellobiose, fructose, glucose, galactose, mannose, trehalose, saccharose, esculin and maltose. It doesn't metabolise mannitol (Johnson et al., 1980; Ozbas, 2004). It was first isolated from children's faeces by Ernst Moro in 1900 and in 1970 it was officially acknowledged as L.acidophilus by Hansen and Mocquat. This term means lactic acid bacteria which can show growth in an acidic environment (Rettger et al., 1935; Ozden, 2008).

L. acidophilus has an antimicrobial effect due to the formation of organic acids (lactic acid, acetic acid, etc.), H₂O, and antibiotic substances (Lactocidin, Acidophilin, Acidolín, Lactocin B). As a result of L. acidophilus's traits, intestinal infections and diseases can be brought under control and negative effects of antibiotic treatment can be eliminated. L. acidophilus is resistant to bile acid and has a strong antibiotic effect on fecal E. coli strains and other intestinal pathogens (Uzun, 2006; Ahmed et al., 2010).

Due to originating from intestinal microbiota, L. acidophilus is usually isolated from infant's faeces. Studies has shown that ingested L.acidophilus, either through a product or pure culture, can be absorbed in intestines, can adapt and survive in gastric juice for two days and longer in bile secretion and faeces (Kiliki, 2008; Ozden, 2008).

**5 Bifidobacterium ssp.**

In 8th Bergey's Manual, Bifidobacterium ssp. was defined as an independent genus by taxonomists and named Bifidobacterium and was included in Actinomycetaceae family. Some of the defined 24 species in 9th Bergey's Manual are B. bifidum, B. breve, B. infantis, B. thermophilum, B. adolescentis, B. longum,

B. pseudolongum, B. coryneforme, B. indicum and B. dentim (Scardovi, 1986).

The use of Bifidobacterium species in fermented and cultured milk and growing knowledge of their taxonomy and ecology resulted in an increase in their popularity in the late 1970s. They grew in popularity considering low acid formation during their shelf life and higher consumption of L(+) lactic acid in comparison with D(-) lactic acid. Among the many probiotic traits that have been attributed to bifidobacteria are a) the induction of immunoglobulin production, b) improvement of food nutritional value by assimilation of substrates not metabolized by the host, c) anti-carcinogenic activity and d) folic acid synthesis (Martinez et al., 2013). Within various probiotic bacteria, Bifidobacterium lactis has been studied intensively and its beneficial roles for host health has been described. B. lactis is preferred for industrial production because of the oxygen and acid tolerance compared with other bifidobacteria species (Janer et al., 2004; Elizaquivel et al., 2011; Akalin et al., 2012).

6 Lactobacillus casei

L. casei is in Streptobacteria subgenus and has a diameter smaller than 1.5 µm, has tendency to form chains and does not have flagella, it is rod shaped, nonmotile and homofermentative. By metabolising pentose, it occasionally forms L(+) lactic acid and acetic acid. L. casei shows rapid growth in media containing % 4 gluconate and forms CO₂. It has an optimum growth temperature of 28-32°C and can grow under 15°C and in some conditions can even show growth at 6-7°C. L. casei can utilise sorbitol and sorbate but shows low fermentation rates with maltose and saccharose. It requires riboflavin, folic acid, Ca pantothenate and niacin for growth. It doesn't form gas and shows strong proteolytic effect after lysis (Kilic, 2008; Ernas & Karagozlu, 2013; Wu et al., 2009).

L. casei is a lactic acid bacteria which can be used in foods worldwide. L.casei is being used as culture or in mixtures to improve sensorial properties and in traditional dairy products such as kefir ve Laban Zeer, cheese such as provolone and parmesan, recent products such as yakult, actimel, gefilus and vifit.

7 Lactobacillus rhamnosus

Due to its probiotic traits, Lactobacillus rhamnosus GG or Lactobacillus GG is the most common microorganism used in dairy products marketed for infant's and children's consumption. Lactobacillus rhamnosus GG, was isolated from human faeces in 1983 and was patented in 1985. Lactobacillus rhamnosus GG is one of the most studied strains and is one of the most common bacteria that is used in probiotic preparations and foods. It has the suffix “GG” because it was discovered in Tufts University by Sherwood Gorbach and Barry Goldin. Lactobacillus rhamnosus GG was first used in the studies at 1990 and was found beneficial to children's health. Due to it's favourable impact on children's health it is widely used with products for infants and children. Some of the main traits of Lactobacillus rhamnosus GG are being indigenous to human intestinal flora, resistance to low pH values and adherence to gastrointestinal track (Canbulat & Ozcan, 2007).

8 Enterococcus faecium/Enterococcus faecalis

Enterococci are singular, double or short chained gram positive cocci. Streptococcus faecalis was defined by Andrewea and Horder in 1906 and Streptococcus faecium was defined by Orla-Jensen in 1919. In 1984 Schleifer and Kilpper-Balz suggested that S. faecalis and S. faecium should be distinguished from Streptococcus genus and considered in Enterococcus genus. Later on, bacteria that are studied in this genus were divided into various species such as; E. faecalis, E. faecium, E. durans, E. avium, E. casseliflavus, E. malodoratus, E. hirae, E. gallinarum, E. mundtii, E. raffinosus, E. pseudoavium, E. flavescens, E. dispar, E. sulphureus, E. saccharolyticus, E. columbae ve E. cecorum (Giraffa, 2002, 2003; Klein, 2003; Ogier & Serror, 2008; Khan et al., 2010).

These bacteria can be found with high amounts in dairy products and other foods and although having extensive biotechnological properties such as; capability to produce bacteriocin, having probiotic traits and usage in dairy industry, there isn’t a consensus on to consider them foodborne pathogens. However recent studies have shown that E. faecalis and some lactic acid bacteria species can cause clinical infections, especially infective endocarditis. E. faecalis can be found not only in human and animal faeces but also on plants and this largely reduces it's usage as a sanitation indicator (Foulquié Moreno et al., 2006; Giraffa, 2003; Kaleli & Durlu-Ozkaya, 2000; Bhardwaj et al., 2008).

Among Enterococcus genus, Enterococcus faecium and Enterococcus faecalis are stated to have probiotic traits. Enterococcus faecium's usage on diarrhea treatment is considered to be an alternative for antibiotic use. The probiotic effect of Enterococcus faecium on humans arise out of reducing the absorption of cholesterol from digestive system (Erginkaya et al., 2007).

9 Lactobacillus gasseri

Lactobacillus gasseri is a rod shaped, non spore forming lactic acid bacteria. This bacteria is a prolific autochthonous microorganism that colonizes the GIT, oral cavity, and vagina in humans. Lactobacillus gasseri is classified as a group B acidophilus complex microorganism, and can be differentiated from group A members by the way of genetic determination and the apparent absence of major surface-layer (S-layer) proteins. The niche-related phenotypes involved incolonization of the human mucosa, including the oral cavity, GIT, and vagina are exhibited by LAB such as L. gasseri and may contribute to or potentiate probiotic activity (Selle & Klaenhammer, 2013). L. gasseri shows to be beneficiary to gastrointestinal system and is stated to have the capability to reduce fecal mutagenic enzymes due to it's probiotic activity. It has the ability to adhere to intestines and has a role in bacteriocin formation and macrophage stimulation. In the view of it's probiotic traits, it can be used in the production of fermented diary products and in commercial preparations (Uzuner, 2012).
10 Streptococcus thermophilus

*S. thermophilus* is a gram positive, circular or elliptical bacteria which has a diameter of 0.7 - 0.9 micron. Morphology of bacteria depends on the genus, environment and growth temperatures. For instance, they have short chains at 45°C, are diplococcus at 30°C but have long chains in cultures that have high acidity. Bacteria in question show symbiotic relationship with *L. bulgaricus* at yoghurt production. At first *S. thermophilus* shows activity in the milk fermented to produce yoghurt, and slightly increases the acidity of the media and consumes oxygen. *L. bulgaricus* starts to grow rapidly in this medium and forms valine which is a necessity for *S. thermophilus*’s growth (Yaygin & Kilic, 1991; Iyer et al., 2010). Besides yoghurt production, they are present in various starter cultures that are used to produce fermented dairy products and cheese (Iyer et al., 2010).

11 Propionibacterium species

In 1906, Freudenreich and Orla-Jensen isolated bacteria from Emmantel cheese and named them *Bacterium acidipropionici* and *Bacillus acidi-propionici*. These organisms are defined based on their capability to form propionic acid. The class Propionibacterium was first introduced by Orla-Jensen in 1909. Classical PAB, also known as “dairy-propionibacteria” are usually present in raw milk, butter and are known for their significant role in maturation process of Swiss type cheeses. Because of their presence in natural flora and starter culture, PAB have a significant role in nonconventional cheese production. Further, by forming propionic acid and acetic acid PAB contributes to the sensorial properties of these products. In milk and other dairy products, *Propionibacterium ferudenreichii*, *Propionibacterium jensenii* and *Propionibacterium acidipropionici* are present prior to the other species of this genus (Cousin et al., 2011).

12 Saccharomyces cerevisiae boulardii

*Saccharomyces boulardii* was discovered by French researcher Boulard in 1923 and is a Gram positive yeast which is a member of Saccharomyces family. It is elliptical or spherical shaped and has a size of 4-8 µm. It forms ascospore and grows in standard yeast mediums with and optimal growth temperature of 37°C and has the capability to assimilate and ferment carbohydrates and can prevent microbial pathogen growth. *Saccharomyces boulardii* shows no pathogenic properties and was isolated from a tropical fruit (lychee fruit) which grows in Southeast Asia and was used for the treatment of diarrhea. In 1962, lyophilised commercial preparation of *S. boulardii* was introduced and notably in France, used as a cure for diarrhea ever since. Diverse arguments are ongoing about it’s being a subspecies of *Saccharomyces cerevisiae* (McCullough et al., 1998; Ertor, 2003; Gultekin, 2004; Czerucka et al., 2007). Lyophilised *S. boulardii* is being used clinically in Europe, Asia, Africa and South America. Preclinical and experimental studies has shown that *Saccharomyces boulardii* has anti inflammatory, antimicrobial, enzymatic, metabolic and antitoxic activities (Ertor, 2003; Billoo et al., 2006; Szajewska, 2012).

13 Probiotic dairy drinks

13.1 Acidophilus milk

Acidophilus milk is a type of fermented dairy product and *L.acidophilus* is used as culture. In the fermented Acidophilus milk production, milk is heat processed at 95°C and goes through homogenisation. Later, it is cooled to 37°C and inoculated with 2-5% commercial *L.acidophilus* pure culture and left for incubation for 12-24 hours. Following incubation, milk is cooled to 5°C and kept under cold conditions. However, in some Acidophilus milk productions, milk goes through the heat process at above 120°C and then cooled and inoculated with 2-5% commercial *L.acidophilus* pure culture. The following process is described above. The purpose of using high temperatures is to eliminate competition and better L.acidophilus growth. In the production of unfermented Acidophilus milk, commercial *L. acidophilus* pure culture is inoculated to cold milk (5-7°C) and milk is kept under cold conditions (Kurmann et al., 1992; Ozden, 2008; Shibly & Mishra, 2013).

Bacteria populate in intestinal system and prevent the activity of harmful gas forming microorganisms. It is beneficial to people with diarrhea and intestinal gas problems (Kilik, 2008). Akpinar (2008) determined that with the use of several aroma substances, improvement in sensorial properties of acidophilus milk is obtainable and reported that strawberry aroma in particular, arouses interest.

13.2 Bifidus milk and Acidophilus-Bifidus milk

Bifidus milk is the first infant product produced with Bifidobacteria and was first produced by Mayer in 1948 at Germany. Today, *Bifidobacterium bifidum* and *Bifidobacterium longum* culture is inoculated with a 10% ratio to milk cooled to the fermentation temperature. Ready to use product has a 4.3-4.7 pH value and contains 10-100 million bifidobacteria in 1 gram (Kurmann et al., 1992). Bifidus milk is easy to digest and is still used for the treatment of gastrointestinal and liver diseases and for constipation (Ozden, 2008). It is produced in Germany and has an acidic and spicy aroma which differs it in taste from other products.

It is produced by using *Bifidobacterium bifidum* and *Bifidobacterium longum* isolated from healthy humans faeces. They form L(+) lactic acid. Milk is standardised and homogenised and kept at 80-120 °C for 5-10 minutes. Then, 10% bifidobacteria culture is inoculated to milk and the milk is left for incubation at 37°C until coagulation. Once it reaches to a pH value of 4.3-4.7, incubation is ended. It is packed and kept in cold conditions. The final product contains 10^4-10^⁶ cfu/ml bacteria. Acidophilus-Bifidus milk, also known as AB culture, is a fermented dairy product which is produced with *L. acidophilus* and *Bifidobacterium* ssp. It contains high levels of viable bacteria with 1:1 bacteria ratio (Kurmann et al., 1992; Ozden, 2008).
13.3 Mil-Mil

Mil-Mil is a Japan originated fermented dairy product. A mixture of Bifidobacterium bifidum, Bifidobacterium breve and Lb. acidophilus cultures is used in the production. It was developed by Yakult Honsha company in Japan. The product is enriched with small quantities of glucose and fructose and carrot juice. Hence, it is rich in provitamin A. Mil-Mil can also be consumed as soup (Kurmann et al., 1992).

13.4 Yakult

Yakult is a probiotic dairy product which is produced with L. casei Shirota strain. L. casei Shirota is resistant to gastric and duodenal acid, can populate and form antimicrobial substances in small intestine and has the ability to improve the activity and quantity of macrophages. L. casei Shirota strain was discovered by Japanese researcher Dr. Shirato in 1935. It is used in commercial products by Yakult Honsha company since 1955. It is proven to be advantageous for health and is on the market in 15 different countries including European countries. Yakult is yet to be on the market in our country. Attention should be paid to yakult and similar products and they should be introduced to the consumers (Kucukcetin & Yaygin, 2000; Gokce & Ustun, 2001).

13.5 Kefir

Kefir is a naturally carbonated, slightly acidic fermented dairy product which is produced with kefir grains and contains complex and specific mixture of yeast and bacteria in a polysaccharide matrix. In Turkish, kefir is defined as “good dairy product which is produced with kefir grains and full or non fat milk is heated up to 90-92°C for at least 3 minutes. Milk is left to incubate until it reaches 0.67-0.72% titratable acidity. It is cooled, packed and kept in cold chain. Acidity of Acidophilin is around 0.67-1.08% and the final product contains 97% Lc. lactis sp. lactis, 2% L. acidophilus and 1% yeast. It has a lower antimicrobial activity than acidophilus milk (Kurmann et al., 1992; Tamime & Marshall, 1997).

Prior to the inoculation at 18-25°C, the homogenised milk is heated up to 90-92°C for at least 3 minutes. Milk is left for incubation until it reaches 0.67-0.72% titratable acidity. It is cooled, packed and kept in cold chain. Acidity of Acidophilin is around 0.67-1.08% and the final product contains 97% Lc. lactis sp. lactis, 2% L. acidophilus and 1% yeast. It has a lower antimicrobial activity than acidophilus milk (Kurmann et al., 1992; Tamime & Marshall, 1997).

13.6 Koumiss-Kumiss

Koumiss is defined as a national beverage produced form mare milk. In Kazakh it is known as Qumuz(is). Different names of koumiss in other languages are: koumis (French), (German), kumys, kumys, кумыс (Russssian) (Ustun, 2009; Dictionary.com, 2013).

Koumiss is produced with traditional methods in houses and small scaled productions while it is produced with industrial methods in sanitariums and large scaled productions. It contains 2% alcohol, 0.5-1.5% lactic acid, 2-4% milk sugar and 2% fat and it tastes like sour ayran. Koumiss is recommended for the treatment of tuberculosis, asthma, pneumonitis, cardiovascular diseases and gynaecological diseases. It is also suitable for weight gain and increasing robustness and energy (Yaygin, 1992; Kink et al., 2000; Karagözlu & Kavas, 2000; Özden, 2008; Ustun, 2009; Dictionary.com, 2013).

13.7 Acidophilin

Acidophilin is a product, produced from cow milk with a process involves the use of a high quality starter culture and it tastes rather acidic. The culture primarily contains Lb. acidophilus. In addition to Lb. acidophilus, it contains Lc. lactis sp. lactis or Lb. delbrueckii sp. bulgaricus. In some cases, kefir culture may be inoculated to the culture with a 1:1:1: ratio (Kurmann et al., 1992; Tamime & Marshall, 1997).

Prior to the inoculation at 18-25°C, the homogenised milk is heated up to 90-92°C for at least 3 minutes. Milk is left for incubation until it reaches 0.67-0.72% titratable acidity. It is cooled, packed and kept in cold chain. Acidity of Acidophilin is around 0.67-1.08% and the final product contains 97% Lc. lactis sp. lactis, 2% L. acidophilus and 1% yeast. It has a lower antimicrobial activity than acidophilus milk (Kurmann et al., 1992; Tamime & Marshall, 1997).

13.8 Miru-Miru

Miru-miru is a dairy product which is produced with a combination of L. casei, L. acidophilus and Bifidobacterium breve and is produced in Japan (Kilic, 2008).

14 Conclusion

Fermented dairy products are crucial to the human diet. Today, due to the increasing demand on safe and functional foods, consumption of new and enriched foods has shown growth to higher rates. In our country, along with high consumption rates of ayran, tendency to consume kefir and other probiotic beverages increases with each passing day. It is quite apparent that with the release of new probiotic and fermented dairy beverages to the market, there will be growing demand on these products. Hence, release of new products to the market and further studies about their functional traits are needed.
