Instituto de Química, Universidade Estadual de Campinas, CP 6154, 13084-971, Campinas – SP, Brazil

(R)-Fluoxetina, um inibidor potente e seletivo da recaptação da serotonina, foi sintetizada em seis etapas, 50% de rendimento total e 99% de excesso enantiomérico a partir do benaldeído via alilação catalítica assimétrica empregando-se o sistema catalítico desenvolvido por Maruoka e colaboradores.

(R)-Fluoxetine, potent and selective serotonin reuptake inhibitor, has been synthesized in six steps, 50% overall yield and 99% ee from benzaldehyde via catalytic asymmetric allylation with Maruoka’s catalyst.

Keywords: fluoxetine, serotonin reuptake inhibitor, catalytic asymmetric allylation

Introduction

The anti-depressants drugs with a 3-aryloxy-3-phenylpropylamine sub-structure (for example, fluoxetine, atomoxetine and nisoxetine) are among the most important pharmaceuticals for the treatment of psychiatric disorders and metabolic problems. In addition, several members of this class have shown promise for the treatment of alcoholism, chronic pain and eating disorders such as obesity and bulimia.

Fluoxetine (1) (Figure 1), a selective serotonin reuptake inhibitor (SSRI), is widely used in clinical practice for the treatment of depression. In fact, the selective serotonin reuptake inhibitors, and particularly fluoxetine (1), have become first line drugs in the pharmacotherapy of patients with depression, whereas tricyclic antidepressants are now considered as second-line agents. This is because the drug possesses tolerability and safety advantages over the tricyclic agents.

In experimental models of inflammation, fluoxetine (1) has been shown to exert anti-inflammatory and pain relieving effects. Fluoxetine (1) [trade name Prozac®] is currently marketed in its racemic form, despite studies showing that the two enantiomers have different activities and rates of metabolization.

Due to its pharmaceutical importance and to the different pharmacological profiles of the individual enantiomers, the development of new strategies for preparing optically pure fluoxetine (1) has received growing interest in recent years. Several methods of enantioselective synthesis of both enantiomers of fluoxetine (1) have been reported and chirality has been introduced via enantioselective hydroxylation, enantioselective epoxidation followed by selective epoxide opening, chemical reduction of ketones and β-ketoesters, stereoselective coupling reaction using chiral auxiliary or chiral catalyst, as well as enzymatic or chemical resolution of benzylic alcohols.

Among the strategies developed for enantiomerically pure (R)-fluoxetine (1), Miles and co-workers described the Ti(OiPr)4/(R)-BINOL asymmetric ene reaction of 3-methylene-2,3-dihydropyran (prepared in 63% yield from 3-furaldehyde as a 3.5:1 mixture with 3-methylfuran) with benzaldehyde which afforded (R)-fluoxetine hydrochloride [(R)-1·HCl] in 6 steps, 56% overall yield and >97% ee from 3-furaldehyde. Recently, Shibasaki and coworkers carried out the total synthesis of (R)-fluoxetine (1) in a multigram scale (4 steps, 67% overall yield, 99% ee) via the catalytic asymmetric epoxidation.

Figure 1. Structure of fluoxetine (1).
of N-methyl-trans-cinnamamide, followed by regioselective epoxide opening.\textsuperscript{16}

The development of chiral Lewis acids or bases for the enantioselective catalytic reactions is one of the most important recent advances in asymmetric synthesis.\textsuperscript{35,36} Enantioselective catalytic allylation (ECA) is one of the powerful C-C bond-forming reactions that have attracted considerable attention in asymmetric synthesis.\textsuperscript{37} In our recent studies, we have employed ECA for the highly stereoselective synthesis of (R)-argentilactone and (R)-goniothalamin from the propargylic aldehyde 2-octinal and (E)-cinnamaldehyde, respectively.\textsuperscript{38-40} Here, we describe a short and high-yielding enantioselective total synthesis of fluoxetine hydrochloride [(R)-1.HCl] from benzaldehyde featuring its enantioselective asymmetric allylation with the Ti(IV)/(R)-BINOL-based catalyst developed by Maruoka and coworkers as the key step.\textsuperscript{41}

**Results and Discussion**

Our approach to the synthesis of fluoxetine hydrochloride [(R)-1.HCl] centered on the treatment of benzaldehyde (2) with the *in situ* generated chiral catalyst (R,R)-A (Figure 2)\textsuperscript{41} in CH\textsubscript{2}Cl\textsubscript{2} at −20 °C for 36 h, followed by the addition of allyltributyltin to provide homoallylic alcohol (R)-1-phenyl-but-3-en-1-ol (3) in 90% yield \([\alpha]_D +53^\circ\) (c=1.1, benzene), lit.\textsuperscript{42} \([\alpha]_D –50.5^\circ\) (c=1.1, benzene) for (S)-isomer, 96% ee (Scheme 2). The enantiomeric purity of 3 was determined to be >99% ee by chiral HPLC analysis [Chiralcel OD column; Hex:iPrOH, 98:2, flow rate = 1 mL min\textsuperscript{-1}, \(\lambda_{\text{max}}\) = 257 cm\textsuperscript{-1}, \(t_R\) = 11.8 min for (S)-isomer, \(t_R\) = 17.2 min for (R)-isomer].

The conversion of 3 to (R)-1-phenyl-1,3-propanediol (4) \([\alpha]_D +66^\circ\) (c=2.4, CH\textsubscript{2}Cl\textsubscript{2}), lit.\textsuperscript{32} \([\alpha]_D +65^\circ\) (c=2.4, CH\textsubscript{2}Cl\textsubscript{2}) was carried out by oxidative cleavage according to the Lemieux-Johnson protocol,\textsuperscript{43} followed by NaBH\textsubscript{4} reduction of the crude aldehyde (87% overall yield). The secondary amino functionality was introduced next via the corresponding mesylate 5 which was regioselectively prepared in 85% yield via treatment of diol 4 with mesyl chloride (1.0 equiv.) and Et\textsubscript{3}N at 0 °C. However, for preparative purposes mesylate 5 was used in the next step without further purification as it proved to be rather unstable to chromatography on silica gel and storage. It was straightforwardly converted to (R)-N-methyl-3-phenyl-3-hydroxypropylamine (6) in 96% yield upon treatment with aqueous methylamine under reflux.\textsuperscript{15} The total synthesis of (R)-fluoxetine [(R)-1.HCl] was concluded after nucleophilic aromatic substitution with 4-chlorobenzotrifluoride by heating it with the sodium salt of alcohol 6 in DMSO at 80-100 °C. Acidification with HCl(g) in ethyl ether led to the (R)-fluoxetine hydrochloride [(R)-1.HCl] \([\alpha]_D –14^\circ\) (c=1, CHCl\textsubscript{3}), lit.\textsuperscript{23} \([\alpha]_D –13.8^\circ\) (c=1, CHCl\textsubscript{3}) in 78% yield (Scheme 1).

![Figure 2. The µ-oxo bis(binaphthoxy)isopropoxytitanium complex (R,R)-A developed by Maruoka and coworkers.](image)

**Scheme 1.** Reagents and conditions: a) (R,R)-A [TiCl\textsubscript{4} (5 mol%), Ti(OPr\textsubscript{i})\textsubscript{4} (15 mol%), Ag\textsubscript{2}O (10 mol%), (R)-BINOL (20 mol%)], allyl-n-tributyltin, CH\textsubscript{2}Cl\textsubscript{2}, 0 °C, 72h (90%, 99% ee); b) OsO\textsubscript{4}, NaIO\textsubscript{4}, ethyl ether: water (1:1, v/v), 2h; c) NaBH\textsubscript{4}, MeOH, 18h (87%, two steps); d) MsCl, Et\textsubscript{3}N, 0 °C, 3h (85%); e) MeNH\textsubscript{2} (40% wt.% solution in water), reflux, 3h (96%); f) i) NaH, DMSO, 80 °C for 1h, then 4-chlorobenzotrifluoride, 80 to 100 °C, 1h; ii) HCl\textsubscript{g}, ether (78%).
In summary, (R)-fluoxetine hydrochloride [(R)-1.HCl] has been synthesized in 6 steps, 50% overall yield and 99% ee from benzaldehyde (2). The route described centered around the catalyst (R,R)-A developed by Maruoka and coworkers for enantioselective catalytic allylation reactions (ECA) not only provides one of the shortest routes to (R)-1.HCl but should be amenable for the preparation of other pharmaceuticals such as atomoxetine and duloxetine.

**Experimental**

**General**

Reagents and solvents are commercial grade and were used as supplied, except dichloromethane and tetrahydrofuran which were distilled from calcium hydride. Chromatographic separations were performed using 70-230 Mesh silica gel. Thin-layer chromatography was used as supplied, except dichloromethane and methanol (0.25 mm layer thickness). IR spectra were obtained on 230 Mesh silica gel. Thin-layer chromatography was performed using 70-230 Mesh silica gel. Optical rotations were measured at 25 °C with Perkin-Elmer 241 instrument. High resolution mass spectra (HRMS) were measured on a VG Autospec-Micromass spectrometer. HPLC analysis was performed using Chiralcel OD column; Hex:iPrOH, 98:2, flow rate = 1 mL min⁻¹, λ max. = 257 nm, retention time = 7.2 min for (R)-isomer in comparison with the racemic samples. IR (film) ν max/cm⁻¹: 3365, 3078, 3033, 2973, 2897, 1637, 1448. ¹H NMR (300 MHz, CDCl₃) δ 7.24-7.34 (5H, m), 5.72-5.86 (1H, m), 5.10-5.19 (2H, m), 4.69-4.74 (1H, m), 2.15-2.53 (2H, m), 2.15 (1H, d, J = 2.6 Hz). ₁³C NMR (75 MHz, CDCl₃) δ 143.7, 134.3, 128.2(2C), 127.4, 125.7(2C), 118.2, 73.2, 43.8, [α]D +53° (c=1.1, C₆H₆), lit.42 [α]D -50.5° (c=1.1, C₆H₆) for (S)-isomer in 96% ee.

(R)-1-Phenyl-3-propanediol (4)³¹, ³²

To a stirred solution of (R)-1-phenyl-3-en-1-ol (3) (550 mg, 3.71 mmol) in a mixture of ethyl ether (12 mL) and water (12 mL) was added OsO₄ (28 mg, 0.11 mmol) and the mixture was stirred for 10 min at room temperature. Powdered NaIO₄ (1.75g, 8.16 mmol) was then added over a 40 min period and stirring was continued for 2h at room temperature. The mixture was poured into ethyl ether (200 mL) and aqueous layer was extracted with ethyl ether (3 x 50 mL). The organic layers were combined and dried with MgSO₄ and filtered. Purification of the residue by column chromatography on silica gel (dichloromethane: methanol = 9:1 as eluent) gave (R)-1-phenyl-3-propanediol (4) (550 mg, 87% yield). IR (film) ν max/cm⁻¹: 3365, 3078, 3033, 2973, 2897, 1637, 1448. ¹H NMR (300 MHz, CDCl₃) δ 7.27-7.37 (5H, m), 7.24-7.34 (5H, m), 4.96 (1H, dd, J = 8.8 and 4.0 Hz), 3.83-3.87 (2H, m), 2.15-2.53 (2H, m), 2.15 (1H, d, J = 2.6 Hz). ₁³C NMR (125 MHz, CDCl₃) δ 144.3, 128.5 (2C), 127.6, 125.6 (2C), 74.4, 61.5, 40.5. [α]D +66° (c=2.4, CH₂Cl₂), lit.³¹ [α]D +65° (c=2.4, CH₂Cl₂).
mg, 1.78 mmol) and triethylamine (260 mg, 2.56 mmol) in dichloromethane (9mL) was added dropwise MsCl (145 μL, 1.87 mmol) under nitrogen at -10 °C, then the mixture was heated to 0 °C. After stirring at 0 °C for 3h, the mixture was poured into ice water (10 mL), washed with 20% H₂SO₄ (7 mL, v/v), saturated aqueous NaHCO₃ (10 mL), and brine, and dried over magnesium sulfate. The solvent was evaporated and the crude reaction mixture was diluted with methanol (10 mL, 40% in water) in THF (10 mL) and then heated at 65 °C for 3 h. After cooling, the solution was diluted with washed, with saturated aqueous sodium bicarbonate and brine, and dried with anhydrous potassium carbonate. Concentration to dryness provides the title compound 6 (476 mg, 81%, 2 steps). IR (film) ν max/cm⁻¹: 3350, 3056, 3026, 2965, 2867, 2807, 1497, 1448, 1388, 1259, 1063, 1033. ¹H NMR (300 MHz, CDCl₃) δ 7.22-7.34 (5H, m), 4.92 (1H, dd, J 8.5 and 3.3 Hz), 3.70-3.80 (1H, br s), 2.83-2.91 (2H, m), 2.44 (3H, s), 1.78-1.96 (7 mL, v/v), saturated aqueous NaHCO₃ (10 mL), and brine, which after concentration, pale yellow oil was obtained. The oil was dissolved in ether and hydrogen chloride gas was bubbled through the solution until white precipitate was formed. The title compound (R)-1.HCl was collected as a white solid (200 mg, 78%). IR (KBr) ν max/cm⁻¹: 2961, 2935, 2799, 2735, 2448, 2448, 1614, 1520, 1324, 1233, 1169, 1101, 1063. ¹H NMR (300 MHz, CDCl₃) δ 9.60 (2H, br s), 7.41 (2H, d, J 8.8 Hz), 7.25-7.34 (5H, m), 6.89 (2H, d, J 8.8 Hz), 4.96 (1H, dd, J 8.0 and 4.8 Hz), 3.04-3.17 (2H, m), 2.62 (3H, s), 2.39-2.58 (2H, m). ¹³C NMR (125 MHz, CDCl₃) δ 159.6, 139.0, 129.0, 128.4(2C), 126.8(2C), 125.7, 124.7(2C), 123.3(2C), 115.8, 76.9, 46.1, 34.5, 33.0. [α]D₉₋₁₄° (c=1, CHCl₃), lit.²⁵ [α]D₉₋₁₃.₈° (c=1, CHCl₃).
