A Direct Approach to Area Change in Continuum Mechanics

In this note we use elementary facts from 3-dimensional linear algebra to demonstrate the formula for area changes under arbitrary linear maps $A: \mathbb{R}^3 \to \mathbb{R}^3$. We do it in general, from a hint given by the well known invertible case, which is an important result used in continuum mechanics. An intrinsic formula for the case when rank $A=2$ is obtained and we finish by showing that we are really exploring a property of the cofactor matrix of $A$ for an orthonormal basis.

Keywords: Cofactor matrix, linear algebra

Introduction

In calculus courses it is standard to consider the lengthy and volume changes corresponding to a mapping $f: \mathbb{R}^3 \to \mathbb{R}^3$. As for the area change, not even the invertible case is usually considered. In this note we approach this matter directly, in the linear case. This is the starting point for generalization to arbitrary smooth functions. And this result is needed when analyzing the properties of the Piola-Kirchhoff stress tensor (Gurtin, 1981, p. 178 and ff., for example).

Let $A$ be a linear mapping from $V$ to $V$, a 3-dimensional real vector space, endowed with an inner product $u \cdot v$ of vectors $u, v \in V$, and oriented by the vector product $u \times v$. Recall that the transpose $A^T$ of $A$ is defined by the equality $Au \cdot v = u \cdot A^T v$, holding for all $u, v \in V$. From the standard properties of the mixed product, $Au \times Av \cdot Aw = (\det A)u \cdot v \cdot w$, and observing that $(\det A)u \times v \cdot w = (\det A) A^{-T} (u \times v) \cdot Aw$, where $A^{-T}$ is the inverse of $A^T$, we get $Au \times Av \cdot Aw = (\det A) A^{-T} (u \times v) \cdot Aw$, valid whenever $A$ is invertible. As $w$ is arbitrary, it follows that

$$Au \times Av = (\det A) A^{-T} (u \times v). \quad (1)$$

This standard result is the starting point of our approach: $Au \times Av$ is always given by a linear mapping acting on $(u \times v)$, even when $A$ is not invertible.

The Direct Approach

Recall that the vectors $u \times v$ and $Au \times Av$ can be seen as normals to span$[u, v]$ and span$[Au, Av]$ respectively. As the oriented area of the parallelogram of sides $u$ and $v$ can be defined by $u \times v$, and the factor for the area change is constant, we realize that if $u' \times v' = u \times v$, then $Au' \times Av' = Au \times Av$. Thus it appears that we can consider a mapping $A^*: V \to V$ defined by the formula

$$A^*(u \times v) = Au \times Av. \quad \text{(2)}$$

Now we show that (2) makes sense and that $A^*$ is linear.

Let $\{u, v, w, r\}$ be a set of vectors in $V$. If we develop the expression $(u \times v) \cdot (w \times r)$, first remembering that $(u \times v) \cdot (w \times r) = u \cdot v \times (w \times r)$ and then performing the triple vector product, we get the well known identity:

$$(u \times v) \cdot (w \times r) = (u \cdot w) (v \cdot r) - (u \cdot r) (v \cdot w). \quad \text{(3)}$$

Now applying (3) to the list $\{Au, Av, w, r\}$ it follows that

$$(Au \times Av) \cdot (w \times r) = (u \times v) \cdot (A^T w \times A^T r). \quad \text{(4)}$$

Choose a positive orthonormal basis $\{e, f, g\}$ for $V$. For $A$ a linear map on $V$, we define $Be := A^T f \times A^T g$, $Bf := A^T g \times A^T e$ and $Bg := A^T e \times A^T f$, and extend $B$ by linearity to all $V$. Then (4) gives

$$(Au \times Av) \cdot (f \times g) = (u \times v) \cdot (A^T f \times A^T g) = u \times v \cdot Be. \quad \text{(5)}$$

or

$$(Au \times Av) \cdot e = B^T (u \times v) \cdot e. \quad \text{(6)}$$

Thus by cyclic permutation of (5) and (6) we conclude that

$$Au \times Av = B^T (u \times v), \quad \text{(7)}$$

and to any $A$ linear we can associate a linear map, which we call $A^*$, such that

$$Au \times Av =: A^*(u \times v) \quad \text{(8)}$$

holds for any vectors $u, v \in V$. Observe that $A^*$ is uniquely determined by $A$, and writing (4) as

$$A^*(u \times v) \cdot (w \times r) = (u \times v) \cdot \left( A^T \right)^T (w \times r)$$

we can conclude that $\left( A^* \right)^T = \left( A^T \right)^T$. Finally, as $(\det A)u \times v \cdot w = Au \times Av \cdot Aw = A^* (u \times v) \cdot Aw = A^T A^* (u \times v) \cdot w$ holds for any three vectors.
\[ A^\top A^* = (\det A) I, \quad (9) \]

using the transpose, \( A \left( A^* \right)^\top = (\det A) I \), we have also

\[ A^* A^\top = (\det A) I. \quad (10) \]

In the invertible case we already know that \( A^* = (\det A) A^{-\top} \) (Chadwick, 1976, Ciarlet, 1988, Greub, 1967, Gurtin, 1981) and, by Ciarlet, 1988, that \( A^* = 0 \) (Greub, 1967, Sinkhorn, 1993) when \( \text{rank} A < 2 \). If the rank of \( A \) is exactly 2 (Sinkhorn, 1993), the defining property (8) also shows that rank \( A^* = 1 \) and because the range of \( A^* \) is the orthogonal complement of the image of \( A \), if we suppose this 1-dimensional subspace generated by the unit vector \( m \), it follows that \( A^* = m \otimes a \) for some vector \( a \) (recall that \( c \otimes b \) is symmetric with nonzero eigenvalues if \( \text{rank} A < 2 \) and \( \text{kernel} A^* = \text{rank} A = 2 \)).

Let \( n \) be a unit vector in the kernel of \( A \). Then

\[ 0 = Au \times An = A^* (u \times n) = [a \times (u \times n)]m = [u \times (n \times a)]m \]

shows that \( a \) is parallel to \( n \). Thus \( A^* = \alpha m \otimes n \) for some nonzero constant \( \alpha \). Now if the list \( \{p, q, n\} \) is a positive orthonormal basis for \( V \), as \( A + \alpha m \otimes n \) is invertible and

\[ \det(A + \alpha m \otimes n) = \alpha \det(A + m \otimes n), \]

then

\[ (A + \alpha m \otimes n)p \times (A + \alpha m \otimes n)q \times (A + \alpha m \otimes n)n = \alpha \det(A + m \otimes n), \]

or

\[ \alpha \det(A + m \otimes n) = Ap \times Aq \times (\alpha m) = \alpha A^* n \times m = \alpha^2, \]

shows that

\[ A^* = \left[ \det(A + m \otimes n) \right](m \otimes n), \quad (11) \]

which is an intrinsic formula for \( A^* \) if \( \text{rank} A = 2 \).

Remark: Recall that the derivative of \( f(A) = \det A \) is given by (Šilhavý, 1997)

\[ \partial_A f(A) = (\det A) A^{-\top} = A^*, \quad (12) \]

whenever \( A \) is invertible, where we have used the standard representation theorem for linear forms.

Let’s call \( \text{Inv} \) the subset of all invertible linear mappings from \( V \) onto \( V \). Thus, if \( \{A_n\} \) is a sequence of elements of \( \text{Inv} \) converging to \( A \),

\[ A_nu \times A_nv = A_n^*(u \times v) \quad (13) \]

shows that \( A_n^*(u \times v) \rightarrow Au \times Av =: A^*(u \times v) \) and we conclude that \( A_n^* \rightarrow A^* \). Thus \( \left[ \det(A_n) A_n^{-\top} \right] \) converges to \( A^* \) whenever \( \{A_n\} \) converges to \( A \), and we have also obtained a formula for the derivative of \( f(A) = \det A \) because we know that \( \text{Inv} \) is dense in the set of linear mappings from \( V \) into \( V \). \( \partial f(A) \) has entries which are polynomials in the entries of \( A \). In particular, if \( \text{rank} A = 2 \), and as in (11) \( m \) is a unit vector orthogonal to the range of \( A \) and \( n \) is a unit vector in the kernel of \( A \),

\[ (A + m \otimes n)(A^* + n \otimes m) = AA^* + m \otimes m, \quad (14) \]

where we have used the elementary facts that \( (b \otimes c)^2 = c \otimes b \). \( A(b \otimes c) = (Ab) \otimes c \). \( (b \otimes c)a = b \otimes (Ac) \) and \( (b \otimes d)e = (c \otimes d)b \otimes e \).

We recall now that \( AA^* \) is symmetric, invertible and positive on the restricted to the range of \( A \). Let \( \alpha^2 \) and \( \beta^2 \) be the eigenvalues of \( AA^* \) (\( \alpha \) and \( \beta \) are the non-negative proper values of \( A \)). Thus the eigenvalues of \( (AA^* + m \otimes m) \) being clearly \( \alpha^2, \beta^2 \) and 1, (14) shows that \( \det(A + m \otimes n) = \alpha^2 \beta^2 \). Finally we observe that if we choose an orthonormal basis \( (u, v, n) \) and the unit vector in the sense of \( Au \times Av \), we can construct a proper rotation \( R \) mapping the range of \( A^* \) onto the range of \( A, n \) into \( Rm = m \) and, for this choice, we have \( \det(A + m \otimes n) \) being positive and equals to \( \alpha \beta \). Thus (11) can be written as

\[ A^* = \alpha \beta Rn \otimes n, \quad (15) \]

the well-known standard formula for \( A^* \). Incidentally, if \( A^* = 0 \) if \( \text{rank} A < 2 \) also follows from (15).

Observe that if \( \text{rank} A = 2 \) and \( A \) is symmetric (or skew-symmetric) then kernel of \( A \) is orthogonal to range of \( A \); if we choose \( m = n \) we obtain directly from (11)

\[ S' = \left[ \det(S + n \otimes n) \right](n \otimes n) = \alpha \beta n \otimes n, \]

if \( A = S \) is symmetric with nonzero eigenvalues \( \alpha \) and \( \beta \); and

\[ W' = \left[ \det(W + n \otimes n) \right](n \otimes n) = |\omega|^2 n \otimes n = \omega \otimes \omega, \]

if \( A = W \) is skew-symmetric with \( \omega \) being its axial vector.

Formulae Using Standard Basis.

Finally in \( \mathbb{R}^3 \) we use the standard basis \( \{i, j, k\} \). The linear mapping \( A \) can be written as \( A = a \otimes i + b \otimes j + c \otimes k \), where \( a, b \) and \( c \) are the images by \( A \) of \( i, j \) and \( k \). Now it is clear that \( A^* = (b \times c) \otimes i + (c \times a) \otimes j + (a \times b) \otimes k \) because \( a \times b = Ai \times Aj = A^*(i \times j) \). Then the matrix of \( A^* \) is the cofactor matrix of \( A \). Now as

\[ A^* A^\top = (b \times c) \otimes a + (c \times a) \otimes b + (a \times b) \otimes c = A^\top A^* = (a \otimes b \otimes c)I, \]

where we have used the well known property \( (u \otimes v)(w \otimes r) = (v \otimes w)(u \otimes r) \), it follows the identity

\[ (a \otimes b \otimes c)v = (a \otimes v)b \times c + (b \otimes v)c \times a + (c \otimes v)a \times b. \]

Observe that if \( \{a, b, c\} \) is a basis for \( \mathbb{R}^3 \), its reciprocal basis is

\[ \left\{ \frac{b \times c}{|a \times b \times c|}, \frac{c \times a}{|a \times b \times c|}, \frac{a \times b}{|a \times b \times c|} \right\}. \]
