Pure zirconium oxide (ZrO₂) nanoparticles with diameters 10-25 nm were synthesized from ZrOCl₂·8H₂O and Zr(SO₄)₂·H₂O with benzyl alcohol as non-aqueous solvent medium using sol-gel method. Sodium lauryl sulfate was added as surfactants to control the particle size. The synthesized ZrO₂ nanoparticles have a mixture of tetragonal and monoclinic structure. The XRD showed the purity of obtained ZrO₂ nanoparticles with tetragonal and monoclinic phase and the crystallite size for ZrOCl₂·8H₂O precursor was estimated to be 18.1 nm and that from Zr(SO₄)₂·H₂O was 9.7 nm. The transmission electron microscopy and scanning electron microscopic studies also shows different sizes of nanoparticles and different morphology depending on the precursor used for the synthesis of ZrO₂ nanoparticles.

Keywords: zirconia, nanoparticles, electron microscopy, precursor and morphology

1. Introduction

Pure zirconia ZrO₂ exhibits three polymorphs of monoclinic, tetragonal and cubic symmetries. The monoclinic phase is stable at room temperature and transforms to the tetragonal phase at 1170 °C during heating, while this phase transforms to the cubic one at 2370 °C. Both transformations are reversible on cooling, although the t → m transition occurs at a lower temperature (about 950 °C). This martensitic transformation, which has been extensively studied, is the basis of the “transformation toughening mechanism” exhibited by zirconia-based materials. About 95% of ferrules used in optical fiber connectors are made of zirconia. Zirconia has unique physical and chemical properties e.g. excellent thermal and chemical stability, high strength and fracture toughness, low thermal conductivity, high corrosion resistance. Both acidic and basic properties of zirconia have been widely used in the fields of structural materials, thermal barrier coatings, oxygen sensors, fuel cells, catalysts and catalytic supports, a possible high dielectric constant material for large scale integrated circuits, and as a gate dielectric in metal oxide-semiconductor (MOS) devices. Ultraline zirconia particles have been synthesized via various methods such as sol-gel processing, chemical vapor synthesis, precipitation from inorganic salt solutions, microwave plasma synthesis, inert gas condensation, combustion synthesis, and laser ablation. In this study we report the synthesis of zirconia nanoparticles synthesized by sol-gel technique in non-aqueous medium.

2. Material and Methods

To 1 mmol ZrOCl₂·8H₂O or Zr(SO₄)₂·H₂O, 2 mmol of benzyl alcohol was added drop-wise, to form a gel. This was followed by the addition of 2 mmol of sodium lauryl sulfate with constant stirring. The product was dried at a temperature of 200 °C for 5 hours and calcined at temperature 600 °C for 5 hours; (Figure 7) shows the method of preparation of ZrO₂ nanoparticles. The samples synthesized were characterized by X-ray powder diffraction (XRD) using (Altima IV Rigaku, X-ray diffractometer and CuKα as X-ray source) transmission electron microscopy was done on (JEN2100F, JEOL, TEM) and scanning electron microscopic studies were carried out on (NNL 200, FEI, SEM) and Perkin-Elmer 1000 FT-IR spectrophotometer.

3. Results and Discussion

3.1. FT-IR spectra

The FT-IR spectra of all the samples were similar. The IR spectrum of typical samples, show a strong broad absorption centered around 3413 cm⁻¹, three sharp absorption bands at about 1630, 1352, and 1044 cm⁻¹, and two weak absorption bands at 580 and 454 cm⁻¹. The bands at about 508 and 493 cm⁻¹ correspond to Zr–O vibration of tetragonal structure. The absorption band located around...
3413 cm$^{-1}$ is associated with the O–H stretching vibration of adsorbed water and hydroxyl group, while the absorption band at 1630 cm$^{-1}$ is due to the bending mode of associated water$^{19}$. The observation of a strong broad absorption at 3400 and sharp absorption band at 1044 cm$^{-1}$ implied that the hydrated molecules could be in several different energetically bonding states.

### 3.2. X-ray diffraction patterns

The XRD patterns of the ZrO$_2$ samples calcined at 600 °C for 5 hours for both precursors ZrOCl$_2$.8H$_2$O and Zr(SO$_4$)$_2$.H$_2$O were similar. The XRD pattern obtained from ZrOCl$_2$.8H$_2$O and Zr(SO$_4$)$_2$.H$_2$O are shown in Figures 1, 2.

![Figure 1. XRD of zirconia nanoparticles synthesized by sol-gel method using ZrOCl$_2$.8H$_2$O as precursor.](image1)

![Figure 2. XRD of zirconia nanoparticles synthesized by sol-gel method using Zr(SO$_4$)$_2$.H$_2$O as precursor.](image2)

Pure ZrO$_2$ shows both monoclinic (θ = 27 and 31.1°) and tetragonal (θ = 30°, 34.9, 50 and 60°) phase. Scherer equation was used to calculate the crystallite sizes for the ZrO$_2$ samples and the crystallite size for ZrOCl$_2$.8H$_2$O precursor was estimated to be 18.1 nm and that from Zr(SO$_4$)$_2$.H$_2$O was 9.7 nm. It should be noted that the precursor has a significant effect on the resulting ZrO$_2$ crystallite size.

### 3.3. TEM, SEM and AFM image

The particle composition was also studied by TEM and SEM and the images are shown in Figures 3-6. Figure 3 shows TEM image of zirconia nanoparticles synthesized by sol-gel method using ZrOCl$_2$.8H$_2$O. The estimated diameters of nanoparticles were found to be 25 nm. It could be seen that the particles have two distinct shapes. One is rod-shaped or nanotubes which are long narrow and appear closed at both ends and the other are much smaller and clustered in a flower shape. Probably these small clusters grow to give the nanotubes observed in the TEM image.

Figure 4 shows TEM image of zirconia nanoparticles synthesized by sol-gel method using Zr(SO$_4$)$_2$.H$_2$O, it could be seen that the particles are uniform and spherical and the average particle size calculated was about 10 nm. There is slight difference in the size of particles obtained from TEM compared to the crystallite size obtained by XRD. This can be attributed to differences of accuracy of measurements of the two different techniques coupled with the fact that the particles obtained from ZrOCl$_2$.8H$_2$O precursor are of two different types and the size difference between these particles is fairly significant. The XRD pattern cannot see these minor differences that can be observed by TEM technique.

Figure 5, shows the SEM image of ZrO$_2$ obtained from ZrOCl$_2$.8H$_2$O precursor and it appears to have a very ill-defined shape. The image appears to show particles like a broken rib cage. Due to this ill-defined morphology, it is possible that the SEM does not give a clear idea of formation of nanoparticles in this case. However, the morphology for the ZrO$_2$ obtained from Zr(SO$_4$)$_2$.H$_2$O precursor is very different. Figure 6, shows the SEM image of ZrO$_2$ obtained...
Siddiqui et al.

It appears to be similar to coral shape. Figure 7 represents the method of preparation of ZrO$_2$ nanoparticles from two different precursors, which are chloride and sulphate. The method of preparation is identical in both the cases. However it is interesting to note that their morphology and nanoparticle size are very different, clearly indicating the role of precursors in the synthesis of nanoparticles.

4. Conclusions

Pure zirconium oxide nanoparticles were successfully prepared by sol-gel method. This is a new method used in the synthesis of zirconia nanoparticles in non-aqueous medium. The results clearly indicate that the morphology and size of ZrO$_2$ nanoparticles is highly dependent on the precursor used. XRD analysis indicated that the nanoparticles closely resembled and had the tetragonal and monoclinic zirconia nanocrystals. The crystallite size for ZrOCl$_2$ precursor was estimated to be 18.1 nm and that from Zr(SO$_4$)$_2$.H$_2$O was 9.7 nm. The TEM results show very different size and shapes for the nanoparticles obtained from the two different precursors.
