Cu$_2$(OH)PO$_4$ microstructures were synthesized by the hydrothermal method using three different types cupric salts (Cu(NO$_3$)$_2$, CuSO$_4$, Cu(CH$_3$COO)$_2$) as raw materials. The X-ray diffraction (XRD), scanning electron microscopy (SEM) and UV-visible-NIR absorption spectra were used to characterize the as-obtained products. The different anions (SO$_4^{2-}$, CH$_3$COO$, NO_3^-$) have different shapes and polarities, which can generate different interactions in reaction bath, induced the difference of structure and morphology of the prepared Cu$_2$(OH)PO$_4$. The Cu$_2$(OH)PO$_4$ microstructures prepared form Cu(NO$_3$)$_2$$\cdot$$3H_2$O showed the best photocatalytic activity induced by near-infrared light to degrade 2,4-dichlorophenol (2,4-DCP) solution. Our work suggests that the active morphological surfaces as well as different coordination environments for the metal ions has an important influence on the photocatalytic performance of Cu$_2$(OH)PO$_4$ microstructure.

Keywords: Cu$_2$(OH)PO$_4$; Morphology; Near-infrared light; Photocatalytic performance

1. Introduction

In the past decades, semiconductor has attracted significant attention owing to their applicability in solar energy conversion and environmental protection$^{1-3}$. However, due to the wide band gaps of the semiconductor photocatalysts, a large part of solar energy cannot be utilized, especially the near-infrared (NIR) region, which accounts for about 44% of the incoming solar energy$^4$. Over the past 30 years, the search for near-infrared light photocatalysts has focused mainly on upconversion luminescence of rare earth materials$^5$$^7$. The rare earth materials can transfer near-infrared light to UV or visible light active photocatalysts to generate the strongly oxidative holes and reductive electrons$^8$. Although this work demonstrated the possibility of using NIR light for photocatalysis, a 980-nm laser had to be used for an overall low conversion, thus exemplifying the limited applicability of this strategy for solar light photocatalysis$^9$. Besides up-conversion materials, only a few of near-infrared photocatalysts have been found, such as Bi$_2$WO$_6$$^9$, carbon quantum dots$^{10}$, WS$_2$$^3$, Cu$_4$(OH)PO$_4$.$^9$. It is still a challenging task to further expand the light absorption range of photocatalysts and develop IR-driven photocatalysts to utilize more solar energy.

Among this near-infrared photocatalyst, copper hydroxypophosphate (Cu$_2$(OH)PO$_4$) has attracted special attention due to its unique near-infrared photocatalytic properties$^{12}$. It has an orthorhombic crystal structure with cell parameters of $a=8.062$, $b=8.384$, and $c=5.881 \text{Å}$ and consists of a PO$_4$ tetrahedron, a Cu(1)O$_6$ octahedron, a Cu(2)O$_3$ trigonal bipyramid, and an OH group between the two Cu species, in which oxygen atoms are shared with each other (shown in Figure S1)$^{13}$. Cu$_2$(OH)PO$_4$ can be synthesized by several methods either the precipitation or hydrothermal methods because it is a simple method and a low-cost technique. Copper nitrate (Cu(NO$_3$)$_2$$\cdot$$3H_2$O) is the most popular agent to form Cu$_2$(OH)PO$_4$ powders$^{14-16}$, however, some different copper sources such as Cu(CH$_3$COO)$_2$ or CuSO$_4$ have been reported for use$^{17-19}$. However, the effect of different types of copper salts on the morphology of Cu$_2$(OH)PO$_4$ has not been reported. It appears that the type of copper salts can control the morphology of Cu$_2$(OH)PO$_4$ and then has an effect on its properties, including its photocatalytic activity.

In this work, we report the effect of cupric salts (Cu(NO$_3$)$_2$, CuSO$_4$, Cu(CH$_3$COO)$_2$) on the structure, morphology and photocatalytic activity of Cu$_2$(OH)PO$_4$ prepared through hydrothermal method. The crystal structures and optical properties of the prepared powders were characterized using X-ray diffraction (XRD) and UV-Vis-NIR diffuse reflectance spectroscopy. Lastly, the photocatalytic properties for the degradation of 2,4-dichlorophenol (2,4-DCP) solution under near-infrared light irradiation were also evaluated.

2. Experimental section

2.1. Synthesis

Cu$_2$(OH)PO$_4$ microcrystals were prepared by a hydrothermal method. In a typical procedure, 20 mmol of Cu(NO$_3$)$_2$$\cdot$$3H_2$O and 10 mmol Na$_3$HPO$_4$$\cdot$$12H_2$O were mixed into deionized
water (ca. 40 mL) under constant stirring for 1h, and the pH of the suspension was adjusted to 7 using 1 mol/L NH₃·H₂O or 1 mol/L HNO₃. The bluish slurry mixture was then transferred to a Teflon-lined stainless steel autoclave, which was filled with deionized water up to 80% of its capacity (50 mL). The autoclave was heated to 120 °C in 30 min and maintained at this temperature for 6 h under autogenous pressure and static conditions. After reaction, the suspension was cooled to room temperature naturally. The deep green crystals were collected and washed several times with distilled water and absolute ethanol to remove impurities. The final products were dried at 50 °C (more than 10 h) for further characterizations. Cu₂(OH)PO₄ prepared from Cu(NO₃)₂·3H₂O, CuSO₄·5H₂O and Cu(CH₃COO)₂·H₂O have been labeled C-0, C-1 and C-2, respectively.

2.2. Characterization

The structural identification and morphology of the Cu₂(OH)PO₄ powders was carried out using an X-ray diffractometer (XRD, D8 Advance, Bruker AXS) with Cu Kα radiation at a wavelength of 0.15406 nm and a field emission scanning electron microscope (FESEM, S-4800, Hitachi), respectively. UV-Vis-NIR diffuse reflectance spectra (DRS) of the samples were recorded on a UV-Vis-NIR spectrophotometer (Cary 5000, Varian) with an integrating sphere attachment within the range of 200-1400 nm and with BaSO₄ as the reference standard.

2.3. Photocatalytic Study

The photocatalytic properties of the as-obtained samples were evaluated by measuring the degradation of 2,4-DCP under NIR light irradiation. A 350-W infrared lamp as the near-infrared light sources where the λ> 760 nm was filtered out during near-infrared light photocatalysis. Typically, 50 mg of sample powder was dispersed in 50 mL of 2,4-DCP aqueous solution (c=20 mg L⁻¹). The scheme diagram of the experimental photocatalytic apparatus was shown in Figure S2. Prior to photoirradiation, the suspensions were magnetically stirred in the dark for 30 min (widespread adoption of time) to attain the adsorption/desorption equilibrium between the dye and the surface of the catalyst under ambient conditions. At varied irradiation time intervals, 3 mL suspension was collected, centrifuged and analyzed by UV-Vis spectroscopic measures (Hitachi UV-3100). The 285 nm wavelength was used to quantify the degradation of 2,4-dichlorophenol.

3. Results and Discussion

The X-ray diffraction (XRD) patterns of Cu₄(OH)PO₄ prepared with three different types of cupric salts are shown in Figure 1, all peaks can be clearly indexed as the
pure orthorhombic phase as all diffraction peaks of these samples are well matched with JCPDS card number 36-0404. The ration difference between diffraction peaks of different samples may be induced by the different exposed crystal faces. The amount of different exposed crystal faces can induce the difference of intensity of diffraction peak. No diffraction peaks for other phases or materials (such as pseudomalachite \([\text{Cu}_5(\text{OH})_4(\text{PO}_4)_2]\) or copper phosphate hydrate \([\text{Cu}_2(\text{PO}_4)\cdot 3\text{H}_2\text{O}]\) are observed in XRD patterns, indicating a high purity and crystallinity of the final products. The average particle diameter is 36.1 nm, 37.5 nm and 38.3 nm for C-0, C-1 and C-2, respectively. The diameter was calculated by using the Scherrer equation, \(D=\frac{k\lambda}{\beta\cos\theta}\), where \(k\) is a dimensionless shape factor, with a value close to unity (0.9); \(\lambda\) is the X-ray wavelength (0.15406 nm); \(\beta\) is the line broadening at half the maximum intensity (FWHM), after subtracting the instrumental line broadening (obtained by deducting the background applying the Jade 6.0 software in our experiment); \(\theta\) is the Bragg angle, which is obtained from the stronger peak in our experiment.

Figure 2 (a-d) show the FESEM images for \(\text{Cu}_2(\text{OH})\text{PO}_4\) with three different cupric salts as raw materials (a) \(\text{Cu(NO}_3)_2\cdot 3\text{H}_2\text{O}\); (b) \(\text{CuSO}_4\cdot 5\text{H}_2\text{O}\); (c) \(\text{Cu(CH}_3\text{COO})_2\cdot \text{H}_2\text{O}\)

Figure 1: X-ray diffraction patterns of \(\text{Cu}_2(\text{OH})\text{PO}_4\) prepared from three different types of cupric salts as raw materials (a) \(\text{Cu(NO}_3)_2\cdot 3\text{H}_2\text{O}\); (b) \(\text{CuSO}_4\cdot 5\text{H}_2\text{O}\); (c) \(\text{Cu(CH}_3\text{COO})_2\cdot \text{H}_2\text{O}\)

Effect of Cupric Salts (\(\text{Cu(NO}_3)_2\), \(\text{CuSO}_4\), \(\text{Cu(CH}_3\text{COO})_2\)) on \(\text{Cu}_2(\text{OH})\text{PO}_4\) Morphology for Photocatalytic Degradation of 2,4-dichlorophenol under Near-infrared light irradiation

To evaluate the optical absorption properties of \(\text{Cu}_2(\text{OH})\text{PO}_4\) with various morphologies, the UV-Vis-NIR absorption spectra were investigated (Figure 3). The results show that the \(\text{Cu}_2(\text{OH})\text{PO}_4\) microstructures prepared with \(\text{Cu(NO}_3)_2\cdot 3\text{H}_2\text{O}\) as raw material (H-0) have very broad absorption band and higher intensity (Figure 3a). The absorption peak of the \(\text{Cu}_2(\text{OH})\text{PO}_4\) microstructures prepared with \(\text{Cu(CH}_3\text{COO})_2\) as raw material (H-2) is located at 520 nm (Figure 3c). It is noteworthy that there is no any absorption in the near-infrared region. Compared to the sample H-2, the \(\text{Cu}_2(\text{OH})\text{PO}_4\) microstructures prepared with \(\text{CuSO}_4\cdot 5\text{H}_2\text{O}\) have very broad absorption band and higher intensity (Figure 3b). The absorption intensity obtained in the presence of the three copper salts is affected by the anion in the following order: \(\text{NO}_3^-\rangle >\text{SO}_4^{2-}\rangle >\text{CH}_3\text{COO}^-\). Remarkable absorption enhancement in near-infrared light region is beneficial for improving photocatalytic activity in this irradiation region.

Figure 4 shows the variations of the photocatalytic degradation of 2,4-DCP as a function of irradiation times, where \(C\) represents concentration of 2,4-DCP at the irradiation time \(t\) and \(C_0\) is the concentration of the 2,4-DCP before irradiation. It is evident that without using any photocatalyst, 15% of the 2,4-DCP molecules were degraded after the light irradiation for 6h (Figure 4a). The H-0 sample possesses enhanced near-infrared photocatalytic activities compared with H-1 sample. The 2,4-DCP —degradation degree for \(\text{Cu}_2(\text{OH})\text{PO}_4\) microstructures (H-1) and \(\text{Cu}_2(\text{OH})\text{PO}_4\) microstructures (H-0) under 6 h near-infrared light irradiation is 35% and 70%, respectively(Figure 4c and Figure 4d ). Figure S3 shows temporal evolution of the spectral changes during photocatalytic degradation of RhB solution over \(\text{Cu}_2(\text{OH})\text{PO}_4\) (H-1) under NIR-light irradiation for various time periods. From Figure S3, it could be seen that with increase of irradiation time in aqueous suspension, the intensity of the absorption peak decreased, which indicated that the

Figure 3: UV-Vis-NIR absorption spectra of Cu$_2$(OH)PO$_4$ prepared from three different types of cupric salts as raw materials (a) Cu(NO$_3$)$_2$•3H$_2$O; (b) CuSO$_4$•5H$_2$O; (c) Cu(CH$_3$COO)$_2$•H$_2$O.

Figure 4: Photocatalytic degradation of 2,4-DCP by Cu$_2$(OH)PO$_4$ prepared from three different types of cupric salts as raw materials under near-infrared light irradiation (a) 2,4-DCP self-decomposition; (b) Cu(CH$_3$COO)$_2$•H$_2$O; (c) CuSO$_4$•5H$_2$O; (d) Cu(NO$_3$)$_2$•3H$_2$O.
Cu$_4$(OH)PO$_4$ (H-1) exhibited good photocatalytic activity. In contrast, the Cu$_4$(OH)PO$_4$ microstructures (H-2) have no near-infrared photodegradation ability to 2,4-DCP (Figure 4b). Therefore, it was observed that rugby-like Cu$_4$(OH)PO$_4$ exhibited significantly higher photocatalytic activity for the photodegradation of 2,4-DCP than that of balsam pear-like and spherical-like Cu$_4$(OH)PO$_4$ microstructures. The mechanism of photocatalytic reaction for Cu$_4$(OH)PO$_4$ under NIR light irradiation is not clear. Huang BB et al. examined the electronic band structure of Cu$_4$(OH)PO$_4$ by performing density functional theory (DFT) calculations, and pointed out that the photogenerated electrons from the Cu$_4$(OH)PO$_4$ trigonal bipyramids that reach the upper three unoccupied bands are easily transferred to the CuO$_4$ octahedra. Our experimental results indicate the active morphological surfaces of Cu$_4$(OH)PO$_4$ microstructures can determine the photocatalytic activity. As is well-known, the surface area has an important influence on the photocatalytic activity. Especially, the photocatalytic activity of nanomaterial is better than the photocatalytic performance of the micromaterial. In this experiment, due to the larger size of particle, thus, the surface area of the sample has the little influence on the observed photocatalytic performance. In addition, the standard deviations of the degradation efficiency were always below 6%, indicating the good reproducibility of the photocatalytic evaluation.

4. Conclusions

The type of cupric salts used as different raw materials can affect the morphology; particle size and photocatalytic activity of the obtained Cu$_4$(OH)PO$_4$ powder. Using Cu(NO$_3$)$_2$·3H$_2$O as raw material, rugby-like Cu$_4$(OH)PO$_4$ microstructures was obtained and exhibited significantly higher photocatalytic activity for the photodegradation of 2,4-DCP. However, when the raw materials are CuSO$_4$·5H$_2$O and Cu(CH$_3$COO)$_2$·H$_2$O, the products showed balsam pear-like and spherical-like morphology, respectively. In addition, the products obtained from CuSO$_4$·5H$_2$O and Cu(CH$_3$COO)$_2$·H$_2$O as raw materials has the poor near-infrared light photocatalytic performance. Our work suggest that the active morphological surfaces of Cu$_4$(OH)PO$_4$ microstructures have an important influence on the photocatalytic activity.
