Abstract
Background: understanding the experience of people who stutter, both in and out treatment, will lead to improved outcomes. Aim: to investigate how stuttering affects the quality of life of children and adolescents who stutter. Method: the Overall Assessment of the Speaker’s Experience of Stuttering - School-Age (OASES-S) was used to assess the impact of stuttering and the Fluency Profile Protocol was used to stuttering severity. Results: these age groups do experience moderate negative impact as measured by the OASES-S. The results showed a tendency toward a positive correlation between severity and the impact of stuttering on quality of life. Conclusion: a better understanding of the impact of stuttering in these age groups provides a needed guide for the development of stuttering treatments and treatment outcomes research.

Key Words: Speech, Language and Hearing Sciences; Quality of Life; Stuttering.
Introduction

Starting in childhood, people who stutter can suffer consequences that affect their lives. The influence of health conditions upon the quality of life (QOL) has gained attention around the world, according to the polices of the World Health Organization. Therefore, understanding the experience of people who stutter, both in and out treatment, will lead to improved outcomes.

Authors 1-2 have developed the Overall Assessment of the Speaker's Experience of Stuttering - Adult version (OASES-A), an instrument based on the International Classification of Functioning, Disability and Health (ICF)3. This classification "(...) replaces the negative perspective of impairment and disability with a positive standpoint".4

A key aspect of the ICF is its focus on QOL. Therefore, the purpose of this study is to investigate how stuttering affects QOL of children and adolescents who stutter.

Method

The study was approved by Ethics Committee and the responsibilities have signed the Consent Term. The corpus are composed by 7 subjects from 7 to 12 years old, six males and one female. The instrument for the assessment of the impact of stuttering - a draft version of the Overall Assessment of the Speaker's Experience of Stuttering for School-Age - (ages 7-12) - OASES-S, was duly authorized for use in this research by the authors. It was translated by a translator and adapted to Portuguese by the brazilian researchers. Stuttering severity was evaluated via Fluency Profile Protocol5.

Results

The results regarding the Assessment of Total Impact show: 57,1% classified as moderate; 28,5% mild-to-moderate and 14,2%, moderate-to-severe (Graph 1).

Furthermore, 71,4% reported feeling "very bad" for being called stutterers. An identical percentage indicated that other people's reaction to their stuttering affects them a little. The majority considered that stuttering does not interfere in the communication with parents (71,4%) or teachers (57,1%). A similar percentage (57,1%) indicated that stuttering does not affect their lives neither their ability to make decisions. Most of them (71,4%) reported that the Speech-language therapy does not interfere negatively in their lives.

According to the Fluency Profile Protocol5, only one subject was not rated as stuttering, according to the reference values, even though he indicated that he feels like stutterer.

To verify the correlation between the variables of the Total Impact of Stuttering and the percentage of speech disruptions (Graph 2) was applied to the Spearman Correlation Test using SPSS - Statistical Package for the Social Sciences for Windows - version 10.0. The correlation coefficient was rho = 0.771 (significant a = 1.0). The results showed tendency toward a positive correlation between severity and impact of stuttering on QOL.

Discussion

Studies\(^6\)\(^-\)\(^8\) show the impact of stuttering on people's life, corroborating our findings. The age groups studied do experience moderate negative impact as measured by the OASES-S and the correlation between overt severity and degree of impact is moderate at best, suggesting that the surface severity does not tell you the whole picture.

The results also demonstrate the importance of Speech and Language Pathology (SLP) therapy for the subjects, similar findings to other authors\(^9\). This study presents "a new instrument for measuring the overall impact of stuttering through assessment of multiple aspects of the disorder."

Conclusion

The study contributes knowledge about the impact of stuttering and supports the use of treatment to improve quality of life in children and adolescents who stutter. It is worth to point out that the instruments - OASES-S and Fluency Profile Protocol demonstrated to be efficient for that purpose. A better understanding of the impact of stuttering in these age groups provides a needed guide for the development of stuttering treatments and treatment outcomes research.

Acknowledgements: this work was part funded by the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq). Thanks to the children and adolescents who participated in this research and to Professor J. Scott Yaruss and Professor Robert W Quesal for allowing the use of OASES-S and for the partnership at this study.
