Created on: June 3, 2019

The Guidelines Project, an initiative of the Brazilian Medical Association, aims to combine information from the medical field in order to standardize producers to assist the reasoning and decision-making of doctors. The information provided through this project must be assessed and criticized by the physician responsible for the conduct that will be adopted, depending on the conditions and the clinical status of each patient.

Lung cancer is the worldwide leading cause of cancer-related deaths in both genders. Pembrolizumab is a IgG4 monoclonal antibody, which is highly selective, humanized, and binds to the programmed cell death protein 1 (PD-1) receptor and blocks its interaction with the PD-L1 and PD-L2 ligands. We conducted a systematic review of the literature, without time restrictions, in the Medline database, using the following PICO: Adult patients with advanced NSCLC; Treatment with pembrolizumab alone or associated with chemotherapy, compared with chemotherapy, except for monochemotherapy with docetaxel and death outcomes (due to any cause) and adverse events. We selected 244 papers to answer the clinical question. The details of the methodology and the results of this guideline are set out in Annex 1.

INTRODUCTION

Lung cancer is the worldwide leading cause of cancer-related deaths in both genders, and smoking is its main etiological factor. The discovery of immunological checkpoints corroborates the hypothesis that ligands present in the tumor modulate the carcinogenesis mechanisms and immune activity of the tumor microenvironment. Among the most studied coregulatory molecules, the PD-1 (programmed cell death 1) and its ligand PD-L1 (programmed cell death ligand 1) stand out.

The PD-1 is a immunologic checkpoint that limits the activity of T cells (lymphocytes) in peripheral tissues. The PD-1 pathway is a immunological control checkpoint that can be coupled by tumor cells to inhibit immune surveillance of the active T cell.

Pembrolizumab is a IgG4 monoclonal antibody that is highly selective, humanized, and binds to the programmed cell death protein 1 (PD-1) receptor and blocks its interaction with the PD-L1 and PD-L2 ligands, which are expressed in antigen-presenting cells and may be expressed by tumors or other cells in the tumor microenvironment, assisting them in preventing of their detection and elimination by the
immune system of the host.

Non-small cell lung neoplasms, without mutations in the epidermal growth factor receptor (EGFR) gene or rearrangement of the anaplastic lymphoma kinase (ALK) gene, with gene expression for PD-L1, are the target of pembrolizumab.

RESULTS

Our study population included a total of 2,877 patients with NSCLC, submitted to pembrolizumab therapy (N=791) and compared to chemotherapy (N=788), or pembrolizumab plus chemotherapy (N=748) compared with chemotherapy (N=550), and followed-up to measure the death and adverse events outcomes for 12 months (Table 1 - Annex I).

Regarding the bias risk of the five studies included, three of them were not double-blind, so the overall risk of the studies can be considered low (Table 2 - Annex I).

META-ANALYSIS

Two RCTs present sufficient data to allow for a meta-analysis, considering results (number of deaths) up to 12 months, comparing pembrolizumab with chemotherapy in advanced NSCLC (Table 3).

The incidence of death was 48.92% (387 in 791 patients) in the Pembrolizumab group and 55.58% in the Chemotherapy group (438 in 788 patients). Pembrolizumab reduced the risk of death by 7% at 12 months [ARR 7%; 95% CI -12% to -2%; p=0.006; I²=0%, NNT=15 (95% CI 9 to 56)], Figure 2.

For this comparison, we also evaluated the adverse events due to any cause, degree ≥3, in the population treated (Table 4).

TABLE 4. ADVERSE EVENTS (GRADE ≥3) - PEMBROLIZUMAB vs. CHEMOTHERAPY.

<table>

</tr>
</tbody>
</table>

The incidence of adverse events ≥3 was 19.5% (154 in 790 patients) in the Pembrolizumab group and 43.4% in the Chemotherapy group (332 in 765 patients). Pembrolizumab reduced the risk of adverse events by 24% at 12 months [ARR = 24%; 95% CI -28% to -19%; p<0.00001; I²=0%, NNT=4 (95% CI 9 to 5)], Figure 2.

Three primary assays comparing pembrolizumab plus chemotherapy versus chemotherapy allow to combine the results and assess the risk of death in 12 months, as the outcome (Table 5).

In all three studies, patients were randomized (1:1) in blocks of four, stratified by tumor proportion score of PD-L1 (<1% vs. ≥1%).

In the meta-analysis of the results of these three studies, there is a significant difference in the

These three RCTs analyzed adverse events of any cause, degree ≥3 in the population treated, for comparison between pembrolizumab plus chemotherapy versus chemotherapy (Table 6).
FIGURE 5. FOREST PLOT COMPARISON: PEMBROLIZUMAB + CHEMOTHERAPY VERSUS CHEMOTHERAPY. RESULTS: ADVERSE EVENTS WITH A DEGREE GREATER THAN OR EQUAL TO 3.

PEMBROLIZUMAB VS CHEMOTHERAPY

In the meta-analysis of three combined studies, there was no significative difference in adverse events with a degree ≥3, in a 12-month follow-up, between both groups (ARR =3%, 95% CI=−0.03 to 0.08; NNT=NS; I²=0%) (Figure 5).

Mortality in 12 months (follow-up: variation of 30 days to 12 months; assessed with: number of deaths in the intervention and control)

CI: Confidence interval; RR: Relative Risk.

**SYNTHESIS OF EVIDENCE**

In adult patients with squamous or non-squamous NSCLC, locally advanced or metastatic, without previous systemic therapy, without mutations in the EGFR gene and gene rearrangement of the ALK, with a score of 0 or 1 in the ECOG performance scale, with at least one measurable lesion evaluated by Recist version 1.1, the treatment with pembrolizumab, associated or not to chemotherapy, compared with standard chemotherapy reduces the risk of death in 12 months by 7% and 8%, respectively. The quality of the evidence that supports this result is high.

For these patients, pembrolizumab reduced adverse events of degree ≥3 by 24% in comparison with chemotherapy, and when associated with it, it showed no difference in adverse events of degree ≥3 in comparison with chemotherapy alone, in up to 12 months. The quality of the evidence that supports this result is high.

**RECOMMENDATION**

The treatment with Pembrolizumab, associated or not with chemotherapy, in adult patients with squamous or non-squamous NSCLC, locally advanced or metastatic, without previous systemic therapy, without mutations in the EGFR gene and gene rearrangement of the ALK, with a score of 0 or 1 in the ECOG performance scale, with at least one measurable lesion evaluated by Recist version 1.1, and PD-L1 expression [Tumor Proportion Score (TPS)] ≥1% (positive PDL-1). High quality of evidence.

**DISCUSSION**

Among human neoplasms for which the investigation of PD-L1 immunohistochemical expression is validated by clinical studies, with an undeniable predictive value of the response to anti-PD-1 therapies available, the non-small cell lung carcinomas stand out. The PD-L1 expression on the tumor-cell membrane is indicated as an aid in the identification of patients for treatment with pembrolizumab. The result of the PD-L1 expression is determined by the percentage of tumor cells with membrane immunostaining (full or basolateral) of any intensity and/or by the percentage of immune cells associated with the tumor with immunostaining of any intensity, according to the type of neoplasia under analysis. Patients with a tumor proportion score (TPS) <1% of the PD-L1 biomarker in the tumor tissue are considered PD-L1 negative and with TPS ≥1% positive.

In the comparison pembrolizumab versus chemotherapy, we included two studies17 that included only patients with TPS ≥1% (PDL-1 positive). However, in the comparison of pembrolizumab plus chemotherapy versus chemotherapy alone, the three studies assessed3-5 included patients with TPS <1% (PDL-1 negative) and TPS ≥1% (1−49% and ≥50%), uniformly distributed between the groups, with an analysis of these subgroups.

It should be emphasized, however, that the greater the number of subgroups analyzed in one sample, the higher the probability of false-positive results; it is also added to that limitation the frequent tendency of...
reporting, after various analyses, only the significant results, which can potentially distort the interpretation of the results. In the event of a positive result, is there effectively a significant difference in the treatment effect, or is it mere occurrence at random (considering the absence of a prior determination of sampling and subsequent statistical power for such difference)?

Considering that: there is a lack of RCTs with a prior determination of sampling comparing positive and negative PD-L1 patients, and the mechanism of action of pembrolizumab in patients with NSCLC.

ANNEX I

The purpose of this assessment is to identify the benefits of immunotherapy with pembrolizumab, associated or not with chemotherapy, in the treatment of patients with locally advanced or metastatic NSCLC, without mutations of the EGFR gene or gene rearrangement of the ALK, with PD-L1 gene expression, in comparison to chemotherapy alone (current standard treatment).

Clinical question

What is the impact of pembrolizumab, associated or not to chemotherapy, on the outcomes of overall mortality (death from any cause) and adverse events in the treatment of patients with advanced NSCLC when compared to chemotherapy alone?

Structured question

Patient – Adult patients with advanced NSCLC;

Intervention – Treatment with Pembrolizumab alone or combined with chemotherapy;

Comparison – Chemotherapy, except monochemotherapy with docetaxel;

Outcomes – Death (due to any cause) and adverse events.

Eligibility criteria

Excluded the outcomes – quality of life, objective response, survival free of progression – analyses of tumor proportion score (TPS) of the PD-L1 biomarker on the tumor tissue were not evaluated.

Randomized clinical trial.

Without time or language restrictions.

Full text available for access.

Search strategies used

The search for evidence will be conducted on Medline virtual scientific information database, using the following search strategy:

(((Pulmonary Neoplasms OR Lung Neoplasm OR Pulmonary Neoplasm OR Lung Neoplasms OR Lung Cancers OR Lung Cancer OR Lung Neoplasm OR Lung Neoplasms OR PD-L1)) AND ((pembrolizumab) AND Random*)) OR (((Pulmonary Neoplasms OR Lung Neoplasm OR Pulmonary Neoplasm OR Lung Neoplasms OR Lung Cancers OR Lung Cancer OR Lung Neoplasm OR Lung Neoplasms)) AND ((pembrolizumab OR PD-L1) AND Random*)).

In the Central/Cochrane databases, the search strategy will be: (Lung Neoplasm OR Pulmonary Neoplasm OR Lung Cancer) AND pembrolizumab.

Extraction of results

We will extract the following data from the studies: name of the author and year of publication, study population, intervention and comparison methods, the absolute number of deaths and adverse events, time of follow-up.

Randomized clinical trials will have their risk of biases analyzed according to the following criteria: randomization, blinded allocation, double-blinding, losses, prognostic characteristics, presence of relevant outcome, time for the outcome, method for outcome measurement, sample size calculation, early interruption, presence of other biases.

The results will be presented as the difference in the risk of death or adverse events between pembrolizumab therapy alone or in combination with chemotherapy, and the treatment with chemotherapy alone. The confidence level adopted was 95%.

The results of the studies included will be combined and meta-analyzed by RevMan 5.3, and the difference in overall risk will be the final measure used to support the synthesis of evidence that will answer the clinical question of this review.

Furthermore, the quality of evidence will be graded as high, moderate, low, or very low using the Grade instrument and taking into account the risk of bias, the presence of inconsistency, vagueness or indirect evidence in the meta-analysis of the outcomes of death and adverse events, and the presence of publication bias. Table 5. Quality of evidence (GRADE).

Explanation: a. 50% with randomization inadequate or not described; only one with blinded
 allocation, three studies without blinding; only with sample size calculation; b. The overall result does not exclude the benefit or harm; c. Test for inconsistency I² equal to 70%; small overlap of confidence intervals; d. The result does not exclude great harm or benefit; e. 2 studies with Jadad = 1 and 2 studies with Jadad >= 3; f. The result does not exclude great harm or benefit.

**Critical evaluation and level of evidence**

All evidence retrieved was evaluated according to their risk of bias (level of error estimated and inherent in the delineation of research or study design used). For the evaluation of the risk of bias of the RCTs, the following items were considered: if the issue was focal, appropriate randomization, blinded allocation, double-blind, losses (>20%), prognostic characteristics, outcomes (time, adequacy, measurement), analysis by intention to treat (ITT), sample size calculation, Jadad scale.

Reflecting the level of uncertainty of the results (effects of benefit or harm), the strength of the evidence can be very low, low, moderate, or strong, depending on:

1. The risks of bias of each individual and meta-analyzed study.
2. The magnitude and accuracy of the results for each outcome analyzed.
3. The relevance, applicability, and generalization of these results.

**Presentation of the results**

In the search for evidence, we retrieved 244 papers, selecting by title and abstract nine studies of immunotherapy with pembrolizumab, associated or not to chemotherapy, in the treatment of patients with NSCLC, compared with chemotherapy alone, of which six studies were accessed since they met the eligibility criteria for analysis of the full text. Of the six studies, five were selected to support this assessment. The grounds for exclusion and the list of studies excluded are available in the references, Figure 6 and Table 9 in the Annexes.

NSCLC = Non-small-cell lung carcinoma; CNS = Central nervous system; AUC = Area under the concentration-time curve; OS = overall survival; SFP = Survival free of progression; PD-L1 = Programmed death ligand 1; TPS = Tumor proportion score of biomarker PD-L1 in tumor tissue; EGFR = Epidermal growth factor receptor; ALK = Anaplastic Lymphoma Kinase; ECOG = Eastern Cooperative Oncology Group; RECIST = Response Evaluation Criteria in solid tumors.

Application of evidence - Recommendation

The available evidence will follow some principles of exposure – it will be by outcome and will have as components: number of patients, type of comparison, magnitude, and precision (standard deviation and 95% CI).

Its strength will be estimated (Oxford®/Grade®) as 1b and 1c (grade A) or strong, and as 2a, 2b and 2c (grade B) or moderate weak, or very weak.

Conflict of interest

There is no conflict of interest related to this review that can be declared by any of the authors.

Final declaration

The Guidelines Project, an initiative of the Brazilian Medical Association in partnership with the Specialty Societies, aims to reconcile medical information in order to standardize approaches that can aid the physician’s reasoning and decision-making process. The information contained in this project must be submitted to the evaluation and criticism of the physician responsible for the conduct to be followed, given the reality and clinical condition of each patient.
