INTRODUCTION

Among several causes of infertility, PCOS stands out due to its frequency, as it affects nearly 5 to 10% of women during reproductive life. Various animal models have been developed to mimic PCOS, among them PCOS induction through continuous illumination exposure is widely used. This induces the animal to an estrous-permanent condition, associated with anovulation, presence of multiple cysts, and an increase in

SUMMARY

OBJECTIVE: To evaluate the ovarian effects of melatonin (Mel) in a rat model of polycystic-ovary-syndrome (PCOS) before and after permanent estrus induction.

METHODS: Thirty-two adult-female rats with regular estrous cycle were equally divided into four groups: 1) GCtrl – at estrous phase. 2) GPCOS – at permanent-estrous phase. 3) GMel1 – treated for 60 days with Mel (0.4 mg/Kg) during permanent estrus induction and 4) GMel2 – rats with PCOS and treated for 60 days with Mel. After that, the animals were euthanized, and the ovaries were removed and processed for paraffin embedding. Sections were stained with H.E. for histomorphometry or subjected to immunohistochemistry for Ki-67 and cleaved caspase-3 (Casp-3) detections.

RESULTS: The GPCOS showed lack of corpus luteum and several ovarian cysts, as well as interstitial-like cells. The presence of corpus luteum and a significant increase in primary and antral follicles were observed in Mel-treated groups, which also showed a decrease in the number of ovarian cysts and in the area occupied by interstitial-like cells. These results were more evident in GMel1. The percentage of Ki-67-positive cells was significantly higher in the Mel-treated groups, mainly in the GMel1, as compared to GPCOS. On the other hand, the percentage of Casp-3-positive cells was significantly lower in granulosa cells of GMel1, whereas it was significantly higher in the interstitial-like cells of GMel2, in comparison to GPCOS.

CONCLUSION: Melatonin administration prevents the permanent estrus state in the PCOS rat model. This effect is more efficient when melatonin is administered before permanent estrus induction.

androgens and estrogens serum levels, along with the reduction in melatonin synthesis.

Studies have been suggested that the reduction of melatonin levels would be responsible for the development of ovarian cysts. In a previous study carried out by our group, we observed an increase in the area occupied by interstitial cells, as well as the lack of corpora lutea in ovaries of rats in the estrous-permanent condition, induced by continuous light exposure. It was also suggested that the interstitial cells of the polycystic ovary of rats probably come from ovarian cysts, due to the degeneration of granulosa cells and the differentiation of theca interna cells. An increase in cleaved caspase-3 immunoreactivity in the granulosa cells of ovarian cysts and the lack of Ki-67 immunolabeling in ovarian interstitial cells have also been identified, suggesting that these cells may originate from another cell type.

Animal and human studies indicate that there is a direct action of melatonin on ovarian function, including a systematic alteration in ovarian steroidogenesis, mainly progesterone synthesis. Pinealectomized rats displayed fertility reduction with a decrease in the number of oocytes, in addition to problems during the gestation period and melatonin serum levels reduction. It has been demonstrated that melatonin treatment is safe due to its low toxicity, even when high doses are administered. Moreover, its administration seems to display satisfactory results in the protection and treatment of reproductive dysfunctions. However, the effects of melatonin in the prevention and treatment of PCOS are still poorly understood.

Thus, this study aims to evaluate the ovarian effects of melatonin (Mel) in a rat model of polycystic ovary syndrome before and after permanent estrus induction.

**METHODS**

**Study design**

This prospective experimental study used thirty-two and three-months-old virgin female rats (Rattus norvegicus albinus) with ± 250g of body weight, provided by the Center for the Development of Experimental Models (CEDEME) at the São Paulo School of medicine, Federal University of São Paulo (UNIFESP/ EPM). This study was initially approved by the Research Ethics Committee at UNIFESP/EPM (Report nº 0179/12), following the guidelines of the Canadian Council on Animal Care.

After a period of seven days of adaptation to the new environment, all animals were subjected to a daily collection of vaginal secretions, for seven consecutive days, in order to evaluate ovarian function. Based on the result of this examination it was possible to observe regular estrous cycles, demonstrating normal ovarian functions. Only rats with regular estrous cycles were included in the study. Then, the rats were randomly divided into four groups: 1) GCtrl - at physiological-estrous phase. 2) GPCOS - at permanent-estrous phase induced by 60 days of continuous illumination (rats with PCOS). 3) GMel1 – PCOS rats daily treated with Mel (0.4 mg/Kg diluted in 500ml of drinking water) during 60 consecutive days, preemptively, and 4) GMel2 – PCOS rats, which remained exposed to 60 days of continuous illumination and treated with Mel. It is noteworthy that the animals of the GMel2 group remained under continuous illumination during a total period of 120 days (60 initial days for the induction of the estrous-permanent condition and 60 additional days during the treatment period).

To obtain animals with PCOS, the rats were placed in wooden boxes, kept in a vivarium under continuous artificial lighting using lamps (Philips, Daylight Model, 40W) that provided about 400 Lux in the region occupied by the rats over a period of 60 consecutive days. The GPCOS animals remained in the same standard vivarium conditions, but their lighting period was from 7 am to 7 pm. After that, the collection of vaginal secretions for seven consecutive days was carried out again, in order to analyze the phases of the estrous cycle. Then, only the animals of the GCtrl that showed regular estrous cycle, as well as the ones of the GPCOS group that were at estrous-permanent condition were used.

Afterward, the animals were anesthetized with 15 mg/kg xylazine (Rompun, SP, Brasil) associated with 30 mg/kg ketamine (Ketalar, SP, Brasil) intraperitoneally and placed in a supine position. Subsequently, after a longitudinal median incision made at the abdomen, the ovaries were removed and immediately fixed for 24 h in 10% formaldehyde (PBS 10mM, pH 7.2). Subsequently, the ovaries were dehydrated in ascending concentrations of ethanol, cleared in xylene, and embedded in paraffin. By using a microtome (Minot, Leica) 5μm-sections were obtained from the paraffin blocks, with a distance of 50μm from each section. Sections were collected on histological slides and subsequently stained with hematoxylin and eosin (HE), whereas others were subjected to immunohistochemical methods.
MELATONIN MAY PREVENT OR REVERSE POLYCYSTIC OVARY SYNDROME IN RATS

After removing the ovaries, the animals were euthanized by deepening the plane of anesthesia and disposed of following current standards at the São Paulo School of medicine (UNIFESP/EPM).

Morphological and morphometric analyses
The evaluation of the slides was carried out at the laboratory of Histology/ UNIFESP/EPM. For the quantification of the parameters evaluated, images were captured by using a high-resolution camera (AxioCam-MCR, Carl Zeiss) adapted to a light microscope (Axioskop, Carl Zeiss) adjusted to a 40X objective lenses and were transmitted to a computer with AxioVision Rel 4.2 software (Carl Zeiss). For the estimation of nuclear volumes of interstitial cells, ten images of each ovary of each rat were obtained, comprising 80 images per group. Posteriorly, the lower and the larger diameter of 10 cells/images were measured and applied to the following formula: 

\[ v = \frac{a^2 \cdot b}{1.91} \]

wherein \( a \) = lower diameter and \( b \) = larger diameter, and 1.91 represents a constant. The determination of the occupied area by interstitial cells was expressed as a percentage, under objective lenses of 10x. Initially, the total ovarian area and the area occupied by interstitial cells in 10 slices of each ovary/animal were measured. Then, the proportion of the area occupied by interstitial cells in relation to the total ovarian area was calculated as a percentage in each section. In this same magnification, the number of ovarian follicles presented in 10 sections of each ovary/animal was counted and classified as primary and antral follicles.

Immunohistochemical analysis
Immunohistochemical reactions for the detection of Ki-67 and Casp-3 were carried out to analyze cell proliferation and apoptosis, respectively. Sections were collected on silanized slides and subsequently dewaxed in xylene and hydrated in decreasing concentrations of ethanol. The endogenous peroxidase activity was blocked by incubating the sections with

![Figure 1](image-url)
3% hydrogen peroxide for 5 minutes. The sections were incubated in a sodium citrate buffer (pH 6.0), 10 mM at 95°C for 20 minutes and non-specific binding sites were blocked with 2% PBS-BSA for 1 hour. Sections were then incubated overnight in the following primary antibodies: anti-Ki-67 (MIB-5, Dako, Denmark, United Kingdom) and anti-cleaved caspase-3 (Asp175-antibody #9661, Cell Signaling Technology, Beverly, USA), diluted at 1:200 and 1:100, respectively. Afterward, the sections were incubated in a biotinylated goat anti-mouse/rabbit (Ig, Duet kit Dako) secondary antibody; reactions were revealed with the streptavidin-peroxidase system (Dako Cytomation, USA) using 3,3′-diamino-benzidine (DAB) as a chromogen and counter-stained with hematoxylin. As a negative control, primary antibodies were replaced by non-specific immunoglobulin (DAKO Cytomation, USA). The frequency of Ki-67 and cleaved caspase-3 immunolabeled cells were expressed as a percentage (%), and a last 500 cells/animal were counted.

### Statistical analysis
Quantitative data were expressed as mean ± standard deviation and evaluated by ANOVA test, followed by Tukey test (using the “GraphPad 5 Prism” software. The rejection level for the null hypothesis was set at 1% (p<0.01), and significant values were marked with an asterisk.

### RESULTS

#### Morphological and morphometric analyses

The morphological results showed lack of corpus luteum and the presence of multiple ovarian cysts in the GPCOS group. Numerous groups of cells containing large and bulky nuclei and well-evident nucleoli were also observed in the GPCOS group. These cells were organized as spherical and cord-like structures with epithelioid aspect, which are typical characteristics of interstitial cells (Fig.1). On the other hand, the Mel-treated groups showed the presence of corpus luteum, as well as an increase in the number of primary and antral follicles, mainly in the Mel1 group (Fig.1 and Table 1). A significant reduction in the number of cysts and in the area occupied by interstitial cells, as well as a decrease in nuclear volume of these cells, were noticed in the Mel-treated groups, mainly in the Mel1 group (Table 1).

Immunohistochemical analysis

The percentage of Ki-67-positive cells (cell proliferation marker) was significantly higher in granulosa cells of the Mel-treated groups when compared to GPCOS group, mainly in the GMel2. Cell proliferation was not observed in interstitial cells of all groups. A weak and not significant Ki-67 immunostaining in the theca cells was also observed in all groups. Conversely, the percentage of Casp-3-positive cells (apoptosis marker) was significantly lower in the granulosa cells of GMel1 (32.50 ± 3.8), in comparison with the PCOS group, whereas it was significantly higher in the interstitial cells of GMel2 (34.04 ± 2.80) when compared to the PCOS group. In addition, a weak and not significant Casp-3 immunoreactivity in the theca cells was noticed in all groups (Table 2).

DISCUSSION

One of the critical hormonal factors in the regulation of follicular development is melatonin. Several authors have demonstrated the presence of their receptors (MT1 and MT2) in the ovarian follicle and support the hypothesis of their role in ovarian physiology. Melatonin may also stimulate follicular development by promoting increased production of insulin-like growth factor I (IGF-I), a major mitogenic factor in granulosa cells. Studies have also demonstrated the effect of melatonin (0.1 mM) on IGF-I receptor expression. Our results showed that rats treated with melatonin presented a greater amount of primary and antral follicles, especially when administered before induction to permanent estrus.

Studies have detected the presence of melatonin in follicular fluid from human preovulatory follicles at concentrations higher than serum levels. High levels of melatonin in follicular fluid seem to play an essential role in the growth and proper maturation of ovarian follicles; in contrast, low concentrations may cause anovulation associated with poor oocyte quality in women with PCOS. However, Shi et al. reported that small swine follicles (<3 mm) contained significantly higher concentrations of melatonin than medium (3 - 8 mm) and large (<8 mm) follicles, which may be related to species-specific reproductive characteristics.

Melatonin has an important antioxidant, anti-poptotic, and anti-inflammatory role. These effects act as a potential factor to protect the oocyte and its surrounding cells against damage caused by oxidative stress, thus inhibiting follicular atresia. According to Sun et al., oxidative stress can cause damage to granulosa cells, increasing the rate of apoptosis of these cells, as well as causing damage to the DNA of oocytes. Our results showed an increase in the number of antral and primary follicles in the melatonin-treated animals when compared to the control group. Moreover, a higher number of ovarian follicles was noticed in the ovaries of animals that received melatonin before induction of permanent estrus state (GMel1). Such findings reinforce the protective effects of melatonin in granulosa cells and ovarian follicles.

High concentrations of melatonin in the preovulatory follicle may be involved with progesterone production, resulting in ovulation and luteinization. In our study, we observed an increase in the number of corpora lutea in melatonin-treated animals, which was more evident in the animals that received melatonin before permanent estrus induction. Zhang et al. demonstrated in humans the action of melatonin on the production of progesterone in granule-lutein cells. This seems to be mediated in part by the increased melatonin-elicited luteinizing hormone (LH) receptor expression. Woo et al. demonstrated the action of melatonin on the modulation of follicular response to LH by increasing the expression of mRNA of LH receptors in granulosa cells in humans. The antral follicles recruited for growth are characterized by the increased expression of mRNA for steroidogenic enzymes, receptors for gonadotrophins, and local regulatory factors.

Studies have demonstrated the action of melatonin on the prevention of apoptosis (cell death mechanism) by inducing Bcl2 expression and reducing the activity of the cleaved caspase-3. Such data corroborate our immunohistochemical findings, which showed a significant decrease in cleaved caspase-3 immunostaining in granulosa cells in animals receiving melatonin before induction to permanent estrus (GMel1). In their study, Sun et al. also observed relatively low positivity of internal theca cells to the TUNEL method (apoptosis/necrosis) in ovarian cysts of sows. Foghi et al. also describe the role of Bcl-2 in the apoptosis of theca cells and interstitial cells in rat atretic follicles. Nevertheless, to our knowledge, there are no papers in the literature that clearly describe the apoptosis process of these cells in rats with polycystic ovaries.

A lower Cyp17a1 immunostaining in theca interna cells has been observed in rats treated with
melatonina, como comparado ao grupo controle. No entanto, em células granulosa e intersticiais, os autores não observaram diferenças estatisticamente significativas entre grupos tratados com melatonina e controles. Nos mesmos grupos, a administração de melatonina induziu uma diminuição no tamanho nuclear e área ocupada por células intersticiais e granulosa, uma vez que houve uma significativa redução em relação ao grupo controle. Além disso, a porcentagem de células Ki-67 positivas foi significativamente maior no GMel1 e GMel2, resultados que corroboram com nossos resultados morfológicos.

CONCLUSÕES

A administração de melatonina previne o estado de estrus-permanente em ratas com SOP. Esse efeito é mais eficiente quando a melatonina é administrada após a indução do estado de estrus-permanente.
