\textbf{OBJECTIVE:} The objective of this study was to analyze the hospitalizations of the elderly for conditions sensitive to primary care (ICSAP) and associated contextual factors, referring to elderly people aged 60 and over, living in municipalities in the Northeast region.

\textbf{METHODS:} Characterized as being an ecological study using data from the Hospital Information System (SIH) and the Basic Attention Information System (SIAB) referring to elderly people aged 60 and over.

\textbf{RESULTS:} The total hospitalization rate was 527,524, with the highest number due to heart failure, followed by cerebrovascular diseases, and infectious gastroenteritis. Analyzing the ICSAP rates with the contextual factors, all were significant. Regarding the coverage of basic care, a similarity occurred between them, and for the rate of the number of consultations among the elderly, despite the greater number of these in the municipalities with higher hospitalization rates, there was no significant difference between them.

\textbf{CONCLUSION:} We conclude that the contextual factors interfere in the conditions of this hospitalization, necessitating, besides the improvement of primary care, an improvement in the living conditions of the elderly population.

\textbf{SUMMARY}

\textbf{INTRODUCTION}

The increase in the elderly population worldwide is currently the subject of many discussions. In Brasil, this has also become relevant, since the country is going through an intense process of population aging. This process brings many changes - psychological, physical, and emotional -, which increases the need for...
attention to the health of elderly individuals, mainly due to the increase in the number of chronic-degenerative diseases. In this context, the health system needs to adapt to this inversion of the population pyramid, including changes in primary care, which is characterized by being the first line of patient treatment. This type of care is paramount in the process of health promotion, prevention of injuries, hospitalizations, and early deaths. Effective primary care is associated with a reduction of costs, user satisfaction, and improved health indicators.1,4

To evaluate and monitor the effectiveness of primary care, a list of Hospitalizations due to Primary Care Sensitive Conditions (PCSC), published in Decree N° 221 of the Ministry of Health (MS), on 17 April 2008, was drawn up and validated in Brasil.2 It comprises a number of diseases and injuries that can be prevented with timely and effective outpatient care, control of acute episodes, or management of chronic conditions and diseases. It lists a set of events that would hardly evolve to the point of requiring hospitalization if approached appropriately in outpatient care promotion, prevention, early treatment, and follow-up.5,6 By studying ICSAP, it is possible to analyze the impact of primary care based on hospitalizations database records.7

Along with these factors, it is important to evaluate the social factors that affect the population health, since studies5,7 have reported that, in addition to the improvement of basic care, it is necessary to assess the socio-economic conditions of the population so that along with the improved access to health there is also improved quality of life as a whole.

Thus, this study aims to study the degree of hospitalizations of elderly individuals in the Northeast region of Brasil, in the period from 2010 to 2015, evaluating the frequency of Hospitalizations due to Primary Care Sensitive Conditions (PCSC) and its possible relationships with contextual factors.

**METHODS**

This is a descriptive ecological study that included elderly individuals aged 60 years or older, residing in the northeast region of Brasil, in the years 2010 to 2015. The sample units are composed of municipalities in the region, which includes nine states and 1,794 municipalities.

We selected data of Hospitalizations due to Primary Care Sensitive Conditions (PCSC) in the municipalities, per location of residence, obtained from the Hospital Information System (SIH), which is based on Hospital Admission Authorizations (HAA type 1).

As a dependent variable, we evaluated the rate of ICSAP in the elderly. This was calculated by the ratio between the number of ICSAP in elderly individuals residents of the municipalities of the Northeast Region and the entire elderly population in these places in the year 2010, multiplied by 6, because it represents the period analyzed (2010-2015), for a cluster of 10 thousand inhabitants.7

In relation to the independent variables, the contextual socioeconomic variables, regarding the last census (2010), were collected from secondary sources: The Institute for Applied Economic Research (IPEA, 2015) and the Brasilian Institute of Geography and Statistics (IBGE, 2015), both in its raw form, as well as transformed into indicators by the United Nations Development Programme (UNDP, 2015). In addition to these variables, we collected data regarding the coverage of basic care in the municipalities and the number of consultations of elderly patients in primary care from the Siab, which used the rate of the number of consultations, consisting of the ratio between the total number of consultations in the years 2010-2015 and the total number of elderly people in the year 2010, multiplied by 6, for a conglomerate of 10,000.

Based on a theoretical and statistical analysis, we selected 11 contextual variables: mean per capita income (income); illiteracy rate in the population aged 18 years old or older (illit.); percentage of the population aged 6 to 14 years old in primary education with no delay (primary-e); degree of formalization of employment (form); rate of activity of individuals aged 25 to 29 years old (actv25-29); unemployment rate of the population 18 years old or older (unemp); percentage of people employed in the agricultural sector (agro); appropriate households (house); dependency ratio (dep_ratio); urbanization rate (urb_rate), and social welfare programs (soc-well).

Since this study is based on official secondary data in public domain, there was no need for approval by the Research Ethics Committee, which followed the guidelines of the Resolution of the National Health Council (CNS) No. 466, December 12, 2012.

**Statistical analysis**

Of the 1,794 municipalities in the Northeast, we carried out a K-means non-hierarchical clustering analysis, which produced clusters of the northeastern
municipalities, based on the chapters of the causes for Hospitalizations due to Primary Care Sensitive Conditions. As a result, three clusters were formed: 1, 2, and 3, with intermediate, low, and high rates of ICSAP, consecutively.

In relation to more than 800 contextual socioeconomic variables, the selection for the multivariate analysis was based on a theoretical analysis of the dimensions of the models of Social Determinants of Health, followed by descriptive analysis, in order to identify those that best differentiate the municipalities and with a distribution closer to normality. Then, we calculated the Spearman’s correlation coefficient between all the variables to select those with the greatest potential to represent the others.

We chose to summarize the set of variables selected by R-type factorial analysis, in which these variables are grouped according to the latent dimensions in its group and interpreted based on what they represent collectively. We used a correlation matrix, the measurement of the adequacy of the sample, the Bartlett test, and anti-image matrix to evaluate the correlation between the variables and the applicability of the factor analysis. The extraction of the factors was done using Principal Component Analysis (PCA), whose number of components extracted was determined by the Kaiser criterion. To facilitate the interpretation of factors, the Varimax rotation method was used.

For the PCA, we included the contextual variables that, from their correlations, were reduced to three components representing the different dimensions related to the contextual level of the Social Determinants of Health. Once we confirmed the applicability of the factor analysis by observing the correlations matrix, with the determinant different from zero (0.006), the anti-image matrix, the Bartlett test (p<0.001) and the Kaiser-Meyer-Olkin index (KMO=0.86), we proceeded to the extraction of components using the 11 variables adequate to it. Based on the Kaiser criterion, we selected three factors that, together, explained 65.3% of the total variance of the variables included in the model.

Therefore, the contextual variables were reduced to three components of the different contextual dimensions of the Social Determinants of Health, component 1, called “Urbanization and Its Reflexes”; component 2, “Favorable Socioeconomic Context”; and 3, “Low Formal Education and Dependence on the State”.

In addition to these contextual variables, we also analyzed the Social Vulnerability Index (SVI), the Human Development Index (HDI) and the Firjan Index of Municipal Development (IFDM) as a way to complement the analysis with the latent variables produced by the factors.

In the analysis of the hospitalization rate of the clusters, along with the contextual variables, we used the analysis of variance with the Bonferroni test for a significance level of 5%.

RESULTS

Evaluating the hospitalization of the elderly individuals due to ICSAP in the given period, the total number of ICSAP in the Northeast region was 1,727,043, with a higher number of cases due to cardiac insufficiency, followed by cerebrovascular diseases and, in third place, infectious gastroenteritis. In the analysis of ICSAP rates using a population of 32,455,176 elderly individuals in a period of six years, we found a total rate of 527,524 hospitalizations for every 10,000 elderly inhabitants - Table 1.

After forming the clusters, according to Figure 1, we observed that in the cluster with the lowest and highest rates of hospitalization, hospitalizations due to heart failure were the most frequent, followed by gastrointestinal diseases and, in third place, by cerebrovascular diseases, which differs from the cluster with intermediate rates, in which infectious gastroenteritis were more frequent, followed by hypertension and, in third place, diabetes mellitus.

After testing the difference between the rates per ICSAP group in elderly patients with the contextual factors, according to Table 2, a significant difference was found in both clusters and the contextual variables. Cluster 3, which has the highest rates of hospitalization, was the one with the best values for the Favorable Socioeconomic Context and higher values for Low Formal Education and Dependence on the State. Cluster 2, which has lower rates of hospitalization, had the best means for the “Urbanization and Its Reflexes”. In relation to the coverage of basic care, there was a similarity between the clusters, and regarding the rate of the number of consultations of elderly individuals, we found that, despite the greater number of consultations in clusters with higher rates of hospital admission, there was no significant difference between them. The VSI was higher for the clusters with intermediate rates. Whereas the IFDM was greater in the clusters with lower rates of
hospitalization, as was the HDI, but the means were not as significantly different for these indexes.

**DISCUSSION**

The results obtained showed that the rate of ICSAP was 527.524 per 10 thousand inhabitants, and the three main causes of ICSAP were congestive heart failure, cerebrovascular diseases, and infectious gastroenteritis. These causes together, considered sensitive to primary care, demonstrate that good attention at this level of care could prevent such events, and these findings may represent a warning to the services of primary health care, so they can identify flaws in the care system of the entire Northeast Region.

On this same premise, studies have reported that the rates of hospitalization due to PCSC serve as indicators that are being increasingly used in the assessment of this type of care, showing that primary care...
services of better quality are associated with lower rates of hospitalization due to CSAP.\textsuperscript{8,9}

The two greatest causes of ICSAP identified in this study corroborate other studies found in the literature and performed in Brasil; however, they evaluate not only the population of elderly individuals but also the population in general. In the evaluation of age groups over 60 years old, illnesses related to the circulatory system are among the main causes of ICSAP.\textsuperscript{1,4,9-13}

The highest rate of hospitalization due to heart failure in the elderly population is confirmed by data published in Brasil, in which this represents the second most frequent cause of hospitalization due to CSAP.\textsuperscript{1,2}

Among the risk factors for heart failure are hypertension, smoking, obesity, sedentary lifestyle, and family history, factors that can be addressed in basic care through health promotion and disease prevention.

Regarding infectious gastroenteritis, the third greatest cause of hospital admissions, they are related to social factors, such as living conditions and adequate sanitation. Studies have reported that these are more often related to the children population, with diseases linked to public health problems in Brasil, with a strong social and economic impact.\textsuperscript{10,12,13}

The clusters with the lowest rates of hospitalization were also those who had the highest mean for the “Urbanization and Its Reflexes” factor, followed by the cluster with the highest rates of hospitalization. In connection with the data found, findings have reported that the process of urbanization and the consequent demographic transition contribute to an increase in chronic non-communicable diseases,\textsuperscript{14} because this process generates industrial development, unhealthy life habits, and environmental pollution, factors that contribute to a greater increase of CNCD,\textsuperscript{10} which explains the greater number of diseases caused by heart failure in the clusters mentioned.

Favorable Socioeconomic Context was also predominant in the cluster with the highest rates of hospitalization. This larger number may be related to greater use of hospital services by elderly individuals, which is related to the higher number of cases of chronic diseases in this stage of life, often with greater intensity and severity, which increases the number of hospitalizations, regardless of social class. In addition, elderly individuals with favorable socioeconomic context also use hospital services often.\textsuperscript{14}

The Low Formal Education and Dependence on the State factor also had the highest mean in clusters with higher rates of hospital admission. This finding is related to the precariousness of services in primary care, since this factor includes people with greater dependence of state health services, and these higher rates may reflect a deficit in primary care, which would entail a greater number of hospitalizations, assuming CSAP was not solved in basic care. In addition, the population with this profile has, consequently, greater exposure to risk factors such as tobacco use, poor diet, among other risk factors related to chronic diseases.\textsuperscript{10,12}

A study carried out in the districts of the municipality of Goiânia also had similar findings, districts that had better socioeconomic contexts had higher rates of hospitalization. The study concluded that this result was motivated by a lack of access to primary health care.\textsuperscript{12}

When analyzing the number of consultations of elderly individuals in primary care, there was no significant difference. The factor does not portray the effectiveness of basic care and its relationship with a greater or lower frequency of ICSAPS in the clusters. It is also important that, in addition to evaluating the primary care, we evaluate the other networks of health services, because their appropriate structuring can provide improvements in the health care of elderly individuals, reducing hospitalizations due to CSAP.

Another study related to the creation of the Family Health Strategy (FHS) with the ICSAP. The results showed no correlation between its expansion and the decrease of ICSAP. Although the population coverage by the FHS has increased in all regional health services of the cities studied, this did not happen evenly.\textsuperscript{15} Studies with 1,622 Brasilian municipalities have also identified a negative correlation between FHS coverage and ICSAP.\textsuperscript{16}

It is stressed that the implementation of the FHS has expanded the coverage of basic care and contributed to the organization of a care model that used the health of the family as a first-line health service. However, this was likely not accompanied by a corresponding improvement in the level of organization and practices of these services, which did not reach the expected levels of effectiveness, and did not follow the improvement in the quality of life of the elderly population, since we observed significant differences between contextual factors and the number of ICSAP in the municipalities.

This is also due to the lack of efforts to improve the integrality of care by many health professionals,
since this principle takes into account not only the disease but the individual as a whole, including the social determinants of health. A study carried out in Porto Alegre reported that, when assessing the effectiveness of the integrality of care, significant problems were found. Some explanations were related; evidence shows that the basic health units still operate under the biomedical logic that focuses on the diseases, and not on the individual, and have lower scores of integrality when compared to the ESFs and to the educational units who have a Multiprofessional Residency. This finding is possibly related to the challenge of breaking away from the traditional care model of such establishments.\textsuperscript{17,19}

The shift towards integrality requires a rupture from the biomedical model through policies of family health prioritization, changes in the building of human resources, and the logic of care that disregards the use of protocols and evidence in the APS care. In addition, the Family Health Strategy also has limitations that may hinder the process for integral care, such as the precariousness of work contracts and the absence of Family Health Support Centers.\textsuperscript{17,19}

Authors have reported that, when assessing the primary care coverage or the number of consultations, it is necessary to check beyond the quality of primary care that it can reflect since there are other factors associated with the results, such as the adequacy of the professionals, the main permanence of physicians; the association to social, economic, political, and environmental determinants; and other aspects of the structural dimension.\textsuperscript{10,16}

The findings of the present study reflect the importance of studying the ICSAP in elderly individuals and monitoring social determinants of health, which will reflect on further assistance to the activity of health promotion among elderly individuals and, consequently, will reduce diseases related to the CSAP and improve the quality of life.

Regarding the limitations of the present study, it is worth noting that this paper is limited to initial hospitalizations, in which there may be diagnostic errors at the time of admission, which could mask some of the causes. However, it should be emphasized that this study corroborates several others in the literature, which confirms the most common findings.

CONCLUSION

We found a predominance of diseases due to heart failure in Hospitalizations due to Primary Care Sensitive Conditions and that contextual factors interfere in the conditions of admission. This makes us conclude that, besides the improvement of primary care, it is necessary to improve the living conditions of the elderly population, because this has great potential for reducing injuries and complications caused by chronic diseases in this population. Therefore, it is essential that public policies work in interventions that ensure care for chronic diseases and strengthen the promotion of healthy aging.
