SUMMARY

OBJECTIVE: To compare the complete blood counts, namely the plateletcrit (PCT) and Platelet-To-Lymphocyte Ratio (PLR) of healthy subjects and those with morbid obesity in the young population.

METHODS: We included 45 patients with morbid obesity (body mass index -BMI- greater than or equal to 45 kg/m²) and 45 healthy subjects (BMI less than or equal to 25 kg/m²) in our study. Blood samples were obtained from the participants following a 12-hour fasting period. Then we evaluated the levels of hemoglobin (Hb), hematocrit (HCT), red cell distribution width (RDW), mean platelet volume (MPV), white blood cell (WBC), PLR, platelet counts, and PCT in the complete blood count.

RESULTS: The morbid obesity group had significantly higher platelet counts and PCT values (p<0.001), and PLR values (p=0.033). The value of WBC was also higher in the obese group (p=0.001). MPV was lower in the obesity group but not statistically significant (p=0.815). No significant difference was found between hemoglobin and hematocrit values in these groups, but RDW values were higher and statistically significant in the obese group (p=0.001).

CONCLUSION: PLR or PCT may be more useful as a marker in determining an increased thrombotic state and inflammatory response in morbid obesity.

INTRODUCTION

Obesity is one of the most common health conditions and its incidence has recently increased, almost escalating to a real epidemic. It is a risk factor for cardiovascular diseases, including angina pectoris, hypertension, congestive heart failure, myocardial infarction, and atrial fibrillation.

Obesity is defined as an excessive or unhealthy buildup of fat and is most likely to have an adverse effect on health. According to the classification by the World Health Organization (WHO) for overweight and obesity based on body mass index (BMI), obesity is defined as a BMI greater than or equal to 30.0 kg/m², and it is classified as morbid when the BMI is greater than or equal to 40 kg/m².

Hypertrophy and hyperplasia of fatty tissue give rise to hypoxia in adipocytes, thus increasing the lev-
el of stress in cells. Consequently, local pro-inflammatory substances are released, leading to inflammation. Inflammation accelerates the development of atherosclerosis and may also induce atherosclerotic plaque rupture and thrombosis.

Complete Blood Count (CBC) is an inexpensive yet simple and easy test to perform. Researchers have studied the effect of platelet indices including platelet count, platelet distribution width (PDW), plateletcrit (PCT), and mean platelet volume (MPV) on the diagnosis, treatment, and follow-up of various conditions. Additionally, a CBC test can be used to evaluate white blood cell (WBC), red cell distribution (RDW), neutrophil-to-lymphocyte ratio (NLR), and platelet-to-lymphocyte ratio (PLR), all of which may give insight into inflammation. PLR is calculated by dividing the platelet count by the lymphocytes.

Platelets have an important effect on inflammation, thrombosis, and atherogenesis. Previous studies have demonstrated increased platelet counts in cardiovascular diseases and vascular complications. Likewise, as an indicator of platelet activation, mean platelet volume (MPV) has been shown to increase in acute myocardial infarction.

Platelet lymphocyte ratio (PLR) has been identified as a biomarker of inflammation and proved to be significant in prognosis. Some studies have shown a relationship between poor prognosis and low lymphocyte count and high platelet count in acute coronary syndrome. Additionally, PLR’s effect on mortality it has been shown to be independent of platelet or lymphocyte counts.

Similarly, a correlation has been found between PLR and adverse outcomes in various cardiac pathologies.

Some of the results were not consistent with recent studies on platelet counts and MPV for individuals with obesity. The calculation of PCT, which gives better information on total platelet mass, is done according to the following formula: PCT = Platelet count x MPV / 10,000. By comparing BMI with whole blood parameters in their study, Furuncuoglu et al. demonstrated that MPV was not statistically significant; however, they found a statistically significant positive correlation between BMI and PCT. To this respect, PCT and PLR values can provide us with more accurate insight into inflammation as well as increased thrombogenic activities.

In this paper, we aim to compare the complete blood counts, namely the PCT and PLR values, of healthy subjects with those of morbid obese individuals in the young population.

**METHODS**

**Study population**

The present cross-sectional study was conducted at Bolu Abant Izzet Baysal University Hospital between March 2018 and October 2018. The local Ethics Committee approved the study protocol. Following the exclusion procedure, we included 45 patients with morbid obesity (BMI greater than or equal to 45 kg/m²) and 45 healthy subjects (BMI value less than or equal to 25 kg/m²) in our study. The mean ages were 33 ± 7 and 33 ± 5 years for the obesity group and the healthy group, respectively. We did not include patients older than 45 years because of the high likelihood of unknown atherosclerosis and comorbidities, both of which could have affected the parameters of complete blood count. Exclusion criteria also included chronic diseases such as chronic renal failure, hypo/hyperthyroidism, coronary artery disease, any hematological abnormality, and medication such as antiplatelet agent and steroid use due to their ability to change the results of a complete blood count. In addition, pregnant women, and patients with anemia and vitamin deficiency (i.e., vitamins D and B12) were excluded from the study. Blood samples were obtained from the participants following a 12-hour fasting period. We then evaluated the levels of hemoglobin (Hb), hematocrit (HCT), PDW, MPV, WBC, PLR, and plateletcrit (PCT) in the complete blood count.

**Statistical analysis**

We carried out analyses using SPSS 18.0 Statistical Package Software for Windows Operating System (SPSS Inc, Chicago, Illinois, USA). Quantitative and qualitative variables were expressed as mean ± standard deviation (SD), and numbers and percentages, respectively. In order to assess the differences between these groups, we used the Student t-test for normally distributed variables, the Mann-Whitney’s U-test for variables without normal distribution, and the Chi-square test for qualitative variables. The correlations of MPV, WBC, PCT, RDW, PLR, and PLT were assessed using the Pearson correlation analyses. We used multivariate linear regression to analyze the value of different baseline characteristics as independent predictors of morbid obesity. ROC
RESULTS

There was no significant difference between study patients and the control group regarding the frequencies of diabetes mellitus, hypertension, smoking, and hyperlipidemia (Table 1). The morbid obesity group had significantly higher platelet counts, PCT values \((p<0.001)\), and PLR values \((p=0.033)\) (Table 2). ROC curve analysis was performed to evaluate PCT and PLR in order to predict morbid obesity. At the cut-off value of \(>0.203\), the sensitivity and specificity of PCT were 80% and 67%, respectively \((\text{AUC} = 0.775, 95\% \text{CI}, 0.678-0.871)\). At the cut-off value of \(>108 \text{mmHg}\), the sensitivity and specificity of PLR were 68% and 54%, respectively \((\text{AUC} = 0.620, 95\% \text{CI}, 0.504-0.736)\). AUC: AREA UNDER THE CURVE, CI: CONFIDENCE INTERVAL, PCT: PLATELET-CRIT, PLR: PLATELET-TO-LYMPHOCYTE RATIO

DISCUSSION

In this study, we compared CBC parameters between morbidly obese patients and healthy subjects.
in the young population. According to our results, platelet counts, PCT, and PLR values were significantly higher in the morbid obesity group. We found that RDW values were significantly higher in the obesity group, and there was no significant difference between hemoglobin and hematocrit values in these groups.

As a chronic inflammation, obesity is associated with an increased atherothrombotic process. A positive correlation between cardiovascular disease and inflammatory markers has been shown in recent epidemiological studies. Previous studies have shown that RDW can be used in the prognosis of cardiovascular diseases and heart failure. Increased RDW is an important predictor of mortality and morbidity in atherosclerotic disease and heart failure, regardless of hemoglobin level. Vayá et al. have shown that RDW values were significantly higher in the obesity group; however, hemoglobin was lower in morbidly obese patients. Therefore, they concluded that increased levels of RDW were due to other causes rather than inflammation.

In the obesity group of our study, platelet counts were significantly higher compared to healthy individuals (p<0.001), but MPV values were not different in both groups. In another study, MPV values were significantly higher in the obesity group than those in the non-obese group; however, there was no significant difference in platelet counts between these groups. Contrarily, Farhangi et al. reported that the difference for MCV values between the obesity and the healthy groups was not significant, and they found the platelet count to be significantly higher.

in the obesity group (p=0.047). Another study has shown that MPV values decrease significantly after weight loss.  

In various studies, researchers investigated the correlation between MPV and platelet count along with weight loss after bariatric surgery. They have found platelet counts to decrease significantly (p<0.0015), but there was no significant decrease in MPV (p=0.34).  

Kurtluturk and Ozsoy reported a significant decrease in platelet counts and a significant increase in MPV after sleeve gastrectomy.

The study results above are different and contradictory regarding MPV and platelet counts. In our opinion, PCT values may provide us with more accurate insight into platelet mass and their functions. PLR may also give more important information about an increased inflammatory status compared to platelet or lymphocyte count alone.

We reported that PLR was significantly higher in the obese group (p=0.033). In several previous clinical trials in which PLR was compared in obese individuals, no statistically significant difference was found between PLR and BMI.

PLR or PCT may be more useful as a marker in determining an increased thrombotic state and inflammatory response in morbidly obese patients. We need to support our findings with larger, prospective, and randomized studies.
