Strabismus surgery in a patient with Saethre-Chotzen syndrome

Correção de estrabismo em paciente com síndrome de Saethre-Chotzen

ABSTRACT

Saethre-Chotzen syndrome is a very rare congenital syndrome characterized by craniosynostosis. The incidence of it is around 1:50,000 live births. Intelligence is usually normal, but a few affected individuals may have mild to moderate mental retardation. Children with Saethre-Chotzen syndrome should be evaluated by members of an experienced interdisciplinary team as treatment usually involves many different specialities. The strabismus surgery in these patients is difficult, because they usually have anomalous insertion and misdirection of the extraocular muscles. Imaging techniques are recommended in order to investigate the anatomical aspects of the extraocular muscles and their insertions.

RESUMO

A síndrome de Saethre-Chotzen é uma doença rara, que pode causar alterações craniofaciais e estrabismo. A incidência é de 1 para 50,000 nascidos vivos. A inteligência costuma ser normal, mas alguns casos podem ter retardo mental. Crianças com essa síndrome devem ser acompanhadas por uma equipe multidisciplinar. A correção do estrabismo nesses pacientes pode ser mais difícil, devido à ocorrência frequente de inserções anômalas dos músculos extraoculares. Recomendam-se técnicas de imagem para avaliar eventuais alterações das inserções e trajeto dos músculos extraoculares.

**INTRODUCTION**

The Saethre-Chotzen syndrome is an autosomal dominant craniosynostosis with an incidence of 1:50,000 live births(1). The anomaly is due to the premature fusion of cranial sutures. Plagiocephaly results from the premature closure of only one side of the coronal suture, leading to facial asymmetry with elevation of the ipsilateral orbit and eyebrow. The intelligence of patients is usually not affected, and the condition may be associated with syndactyly and strabismus.

**CASE REPORT**

T.A.L., a 13-year-old female patient from Mauá/SP, Brazil, was referred to the Strabismus Unit of the University Hospital of São Paulo University (HCFMUSP) with a history of abnormal head position since birth. She was followed-up from the age of 8 years in the Medical Genetics and Neurosurgery units, where she received the diagnosis of Saethre-Chotzen Syndrome. In July 1998 she underwent surgery to correct craniosynostosis, after being diagnosed with plagiocephaly.

**Medical History**

Birth by caesarean delivery at term without complications, weighting 3750 grams. Her neuropsychomotor development was normal.

**Ophthalmic Examination**

Corrected visual acuity of 0.2 (+4.00 SD, -1.00 CD X 90) in the right eye and 0.6 (+1.00 SD) in the left eye. Biomicroscopy and fundus examination were normal.

The first examination of extrinsic ocular muscles, performed on October 5th, 2001, showed:

- Monocular central fixation, stable in both eyes.
- Binocular fixation = without correction and with far and near optical correction, right exotropia (XT) and hypotropia, deviation of the right eye.
- Right exyclotropia 5° in the double Maddox rod test.
- Alternate prism cover test: With correction (Figure 1A) and versions (Figure 1B).

During the examination it was noted that the patient tilted her head towards the right shoulder. Also, in the evaluation of

![Figure 1A. First examination of extrinsic ocular muscles (October 5th, 2001)](image1)

Upper boxes show measures with right eye fixation and lower boxes show measures with left eye fixation. Measures for near fixation were done in the straight ahead and down gaze positions.

![Figure 1B. Examination of extrinsic ocular muscles (October 5th, 2001)](image2)

Upper boxes show measures with right eye fixation and lower boxes show measures with left eye fixation. Measures for near fixation were done in the straight ahead and down gaze positions.

![Figure 2A. Examination of extrinsic ocular muscles (August 21st, 2002)](image3)

Torticollis was absent.

- Binocular rotation: Underacting right inferior oblique muscle, -1 in both eyes
- Overacting superior oblique muscles, +3 in both eyes

Slight lowering of both eyes in adduction
Approximately 56% of patients with craniosynostosis have strabismus.1 In these patients, the extraocular muscles may be absent or may present changes in thickness, fibrosis, and anomalous paths and insertions. Malformation of the orbit, amblyopia and intracranial hypertension syndrome may occur.2 In the case presented here, treatment and surgical planning were difficult due to the anomalous insertion of extraocular muscles, as well as the facial asymmetry.

Imaging tests such as MRI, CT and ocular ultrasonography can be used to support surgical planning in cases of strabismus associated with craniosynostosis.2 With these tests, surgical planning can be done with previous knowledge of the anatomic changes of extraocular muscles, thus avoiding unnecessary incisions and inadvertent muscle injury and reducing the number of procedures needed to correct deviations and improve results. In the case presented here, imaging tests did not show changes in muscle paths, as the imaging technique was not specifically intended to study the problem, but those changes were then found during surgery. In such cases, the physician should state their diagnostic hypothesis when requesting the imaging test, so that the paths of affected muscles can be studied more accurately.

The orbital asymmetry, with the right orbit lower than the left, and the transoperative findings of anomalous muscle insertions and paths can perhaps explain some clinical findings which were initially considered as paradoxical, such as torticollis and anisotropy not confirmed by objective data measurement with prisms.

**CONCLUSION**

This case report illustrates the surgical difficulties found in such cases: The anomalous muscle paths were only detected during the operation, even though imaging tests had been performed preoperatively, failing to find the anomaly. Requests for imaging tests should include proper instructions to the radiologist as to what to investigate, so that the results can actually support surgical planning.
