**Abstract**

*Gotocotyla acanthura* (Parona & Perugia, 1896) Meserve, 1938 collected from the gills of *Pomatomus saltatrix* from the coast of the state of Rio de Janeiro state was analyzed using scanning electron microscopy (SEM). The study demonstrated the presence of a buccal cavity, a genital atrium on the ventral surface and a muscular structure on the dorsal surface at the level of the body constriction. An elongated haptor with 80 to 120 pedunculated clamps symmetrically distributed in two rows, with rib-like thickenings and a curved lappet bearing a pair of hooks at the posterior extremity of the body were also observed. The cirrus could be seen protruding from the genital atrium, armed with pectinate spines along its length and presenting up to eight pointed spines around the genital atrium.

**Keywords:** Monogenea, parasites, fishes, surface topography.

In Brazil, monogeneans collected from *Pomatomus saltatrix* (Linnaeus) were described as *Gotocotyla travassosi* by Kohn et al. (1971). This species was then transferred, by Lebedev (1984), to the genus *Swakopella*, which is characterized by the presence of two lateral vaginae and an additional dorsal sucker. Hayward and Rohde (1999) examined the type material of *G. travassosi* and reported that the measurements of the copulatory organ and its spines in the original description were incorrect. Hayward and Rohde (1999) did not observe the lateral vaginae described by Lebedev (1984) and thus, synonymized *G. travassosi* with *G. acanthura* (Parona & Perugia, 1896) Meserve, 1938, which was originally described from *Brama brama* (Bonnaterre) in Italy. Since then, this species has been reported in different species of scombrids and perches in the Atlantic, Indian and Pacific Oceans (Ramalingam, 1961; Koratha, 1955; Lebedev; Parukhin, 1969; Young, 1970; Bravo-Hollis; Caballero-deloya, 1979; Shen; Qiu, 1995; Willliams; Bunkley-Williams, 1996).

Studies on species of Monogenea by means of scanning electron microscopy (SEM) have been used to supplement observations using light microscopy and have helped to provide information of great accuracy regarding species morphology. In the present paper, ultrastructural data obtained from SEM studies on specimens of *G. acanthura* collected from *P. saltatrix* were used to provide detail and extend the current knowledge of the morphology of this species.

Monogeneans collected from the gills of *Pomatomus saltatrix* from the coast of the State of Rio de Janeiro, Brazil, were fixed under gentle cover glass pressure in 5% formaldehyde. Some of the samples were stained with Langeron's alcoholic-acid carmine, dehydrated in an ethyl alcohol series, cleared in beechwood creosote and mounted in Canada balsam. The specimens were observed under a Zeiss Axioskop 2 Plus microscope and the images were captured using a SONY MPEGMovie EX DSC-S75.

digital camera. The specimens studied have been deposited in the Helminthological Collection of the Oswaldo Cruz Institute (CHIOC nº 37.526, 37527a-b, 37528) in Brazil.

A further ten samples of mature worms were prepared for SEM as follows. The specimens were firstly fixed for one hour at 4 °C, in 2.5% glutaraldehyde in 0.1 M sodium cacodylate buffer (pH 7.2), and were then washed in the same buffer three times for 15 minutes and post-fixed for one hour at room temperature with 1% osmium tetroxide in the same buffer. The specimens were then dehydrated in an ascending acetone series, dried by means of the critical point method with CO₂, mounted with silver adhesive tape on aluminum stubs and coated with a layer of gold of thickness 60 nm. The samples were examined under a Zeiss DSM 940 and a Jeol JSM-6390LV SEM, operated at 15 kV. The images were digitally captured onto an IBM-PC and processed using Adobe Photo Shop 7.0 software.

Results

The specimens of *G. acanthura* presented an elongated body that was constricted near the anterior extremity, with a haptor in the posterior portion as an extension of the body (Figure 1a and Figure 2e). Transverse striations and ridges, probably due to muscle contraction, were seen on the ventral body surface (Figures 1b,c).

The buccal opening (mouth) is subterminal and ventral, at the anterior extremity of the body (Figures 1b,c). The tegument of this region is composed of two articulated jaws (Figures 2c,d) supported by a median sclerite (Figure 2c). Three to five rib-like thickenings is to facilitate partial interlocking of adjacent clamps. The function of the well-developed muscular structure on the dorsal surface of the body elucidated that of *G. acanthura* in the present study showed that the everted cirrus with pectinate spines and the muscular structure on the dorsal surface of the body elucidated the morphological features.

In their review of Gotocotylidae, Hayward and Rohde (1999) pointed out that the specimens studied using SEM that had been presented as *G. bivaginalis* (RAMALINGAM, 1961) by Ramasamy and Hanna (1989) actually belonged to *G. acanthura*. Considering that no slides are available, it is not possible to confirm this statement. As in the present study on *G. acanthura*, the specimens studied by Ramasamy and Hanna (1989) presented clamps with four to five prominent rib-like thickenings. In the opinion of Ramasamy and Hanna (1989), the likely function of the thickenings is to facilitate partial interlocking of adjacent clamps.

Discussion

Examination of the tegument of *G. acanthura* in the present study showed that the everted cirrus with pectinate spines and the muscular structure on the dorsal surface of the body elucidated the morphological features.

Acknowledgements

The authors are grateful to Anna Kohn, from the “Laboratório de Helmintos Parasitos de Peixes, Instituto Oswaldo Cruz, Brazil” for reading the manuscript and for the suggestions made, to Marielle Delfim Pereira from the “Laboratório de Biologia Estrutural, Instituto Oswaldo Cruz, Rio de Janeiro, Brasil” for technical assistance and to Dr. Luis Souhami from McGill Hospital, Montreal, Canada for reviewing the English of the manuscript.
