Use of noninvasive positive pressure ventilation and spinal anesthesia during hip replacement arthroplasty in a patient with severe chronic obstructive pulmonary disease. Case report

Introduction

Chronic obstructive pulmonary disease (COPD) is an increasingly prevalent condition in the overall population and is considered an independent risk factor for cardiopulmonary mortality and morbidity at postoperative period. While general anesthesia has been associated to a higher risk of complications during and after surgical procedure, regional anesthesia has the advantage of avoiding tracheal intubation and worsening of the postoperative pulmonary function. With improvement of anesthetic techniques, of drugs utilized and of intra- and postoperative cares, it became possible to reduce morbidity and mortality of patients, classically viewed as contraindicated for surgery. Interaction between the clinical, surgical and anesthetic teams becomes essential in the management of such patients.

The objective of this study was to present a case of application of noninvasive mechanical ventilation (NIMV) during hip arthroplasty of a patient with severe COPD, associated to regional anesthesia (spinal).
CASE REPORT

A male, 81 years old, 75 kg patient was admitted after a fall from his own height, presenting with pain, external rotation deformity and shortening of the lower right limb and was diagnosed as displaced femoral neck fracture Garden IV (Figure 1) with indication for partial hip arthroplasty. Bearer of severe COPD, presenting respiratory function test (RFT) with a forced expiratory volume in 1 second (FEV₁) <20%, while using domestic oxygen therapy, corticoid therapy and presenting with dyspnea at minimal efforts.

Furthermore, the patient had undergone a coronary angioplasty with placement of a drug-eluting stent two years earlier. As comorbidities he has hypothyroidism and diabetes mellitus type II with regular use of prednisone, bamilifylline, inhalatory β-agonist and ipatropium, acetylsalicylic acid and pantoprazole.

At pre-operative evaluation he was bedridden, with pain in the lower right limb, tachypnea, hemodynamically stable and with 88% oxygen saturation. Patient alternated use of NIMV/ Bi-level Positive Airway Pressure (BIPAP) with nasal 3L/min oxygen O₂. Complementary exams showed hematocrit 36%; normal leukogram and coagulogram; echocardiogram with mild ventricular dysfunction; chest X-ray (Figure 2). arterial pre-operative gasometry under O₂ at 4 L/min showed pH = 7.38, pCO₂ - 54 mmHg, pO₂ - 93 mmHg, HCO₃⁻ - 31.2 mmol/L, base excess: 4.9, SpO₂: 96%.

After monitoring by cardioscope, noninvasive pressure and pulse oximetry, a peripheral venous access was punctured and cefazolin 2 g and hydrocortisone 200 mg were administered. NIMV with BIPAP under full face mask (Figure 3) was administered with the parameters expiratory positive airway pressure (EPAP) of 7cmH₂O, inspiratory positive airway pressure (IPAP) 15 cmH₂O and O₂ flow of 3 L/min.

Diazepam 1 mg and cefotamine 5 mg both intravenously, for positioning on left lateral decubitus were administered. Simple isobaric spinal anesthesia was given in the subdural space in the L₃-L₄ spaces, needle 25G. First trial, liquor was clear and injection of isobaric bupivacaine 16mg with final sensory level at T₁₀. Continuous infusion of dexmedetomidine 0. 2 µg/kg/min was begun for sedation. The surgical procedure was comprised of partial bipolar arthroplasty of the hip with the contemporary technique of femoral stem cementing, on the left lateral decubitus for some 75 minutes. During implant of the medullary cemented prosthesis, patient presented with temporary oxygen desaturation to 80% and bronchospasm which was reverted by adjusting parameters to

Figure 1 – Non-pathological fracture of the right femoral neck.

Figure 2 – Chest x-ray disclosing pulmonary hyperinsufflation, elevation of the right phrenic dome previous lobectomy due to benign pulmonary nodule and calcified hilar mass also to the right.

Figure 3 - Patient using noninvasive ventilation in the intra-operative.
IPAP 17 cmH₂O and EPAP 8 cmH₂O associated with administration of inhalatory β-agonist and ipatropium. He was then referred to intensive care unit (ICU) hemodynamically stable, with a 94% saturation on BIPAP, lucid, oriented and painless.

Postoperative progressed with hemodynamic stability; good control of pain using dipyrone associated to tramadol and continued use of NIMV/BIPAP during the first 24 hours following procedure. Thereafter, the patient resumed use of nasal oxygen and intermittent NIMV. Post-procedure arterial gasometry showed: pH – 7.38, pCO₂ - 54 mmHg, pO₂ - 63 mmHg, HCO₃⁻ – 31.2 mmol/L, base excess: 4.8, sO₂₂: 92%. Patient was transferred to the semi-intensive care unit 10 days after procedure.

**DISCUSSION**

Prevalence of COPD is estimated at 6% and became the main cause of mortality among respiratory diseases.1,4 Adequate pre and intraoperative assessments estimates of surgery cost-benefit, type of anesthesia, ventilation assistance and hemodynamic support increase survival of these patients at postoperative.

The patient presented a pulmonary condition with severe restrictions; however acute disease worsened the condition requiring a planning of intraoperative ventilation support appropriate for the situation.

While, among the general population the rate of postoperative pulmonary complications ranges from 5% to 12%5-6, in patients with COPD, the number and type of complications increase substantially (37% of cases)3 for this reason in the decade of 1970, some authors recommended that only life-saving surgeries should be carried out in patients with FEV₁ < 0.5L. The option of not operating this patient was considered, because of the severity of this disease it is difficult to carry out a randomized study with a large population in order to evaluate the morbidity/mortality inherent to the ventilation mode.

Regional anesthesia is described as the preferential mode for patients with COPD and respiratory failure when compared to general anesthesia.2 Factors of general anesthesia such as atelectasia, cephalic displacement of the diaphragm and loss of respiratory stimulus are attributed to this worsening.8 Notwithstanding that regional anesthesia is also associated to a decrease of the respiratory function, occurrence of such an event is less frequent and intense when compared to general anesthesia.

General anesthesia, in addition to be considered a risk factor for mortality in hip surgery, is associated to complications and worsening in the ventilation pattern at intra- and postoperative of patients with COPD.9 Although regional anesthesia is suitable for hip surgery, factors related to its use, such as positioning, surgical stress, sedation and neuromuscular block may worsen the respiratory condition, therefore the need arises for adequate intraoperative support in patients with a previously poor pulmonary function, such as patients with COPD.10

The combination of regional anesthesia associated to NIMV during intraoperative of patients with COPD and respiratory failure was recently described in literature11-15, with few reports on hip arthroplasty.12-13

NIMV is a well-known method for decrease of mortality, improvement of respiratory distress and correction of blood gas disorders in exacerbation of COPD.16-17 During surgery, tracheal intubation may also be used as a support ventilatory mode in respiratory failure and in COPD. Although it is not associated to an increase of mortality in patients with COPD admitted to ICU18 tracheal intubation may entail spirometric worsening at postoperative of healthy patients.19 However it is not known whether this worsening observed in the spirometric pattern of healthy patients, also takes places in patients with COPD and whether it may contribute to increased mortality or postoperative cost – when compared to patients who have used NIMV in the intraoperative.

Management of an obese patient with severe COPD submitted to hip arthroplasty under spinal anesthesia and BIPAP was previously described.32 Risks of general anesthesia with tracheal intubation in this population are reported, as well as need for compliance to the method as the essential problem. In the case reported, previous
knowledge of the patient’s tolerance regarding NIMV facilitated its use. The patient of the study was discharged 7 days after surgery, while the patient in this case remained in the ICU for 10 days. It is noteworthy that although intensive care length of stay is longer in the report on our patient, he showed more severity factors in surgery (lower FEV1, older, obesity).

NIMV has also been reported in patients with acute ventilation impairment. One case of worsened chronic respiratory failure, submitted to spinal anesthesia and support with NIMV avoiding general anesthesia, was reported.13 Warren et al. described the case of a patient with myasthenia gravis and acute respiratory failure submitted to obstetric surgery under peridural anesthesia using noninvasive ventilation support.14 The position required for the surgical procedure often involves undesirable and intolerable ventilatory alterations in pulmonary sick patients.10 An English group described use of NIMV in a severe COPD patient submitted to resection of a carcinoma of the rectum, under spinal anesthesia in lithotomic position.11 NIMV allowed the patient to tolerate the respiratory restriction imposed by the position of lithotomy, avoiding general anesthesia.

In view of this evidence, NIMV has been evaluated in patients with chronic and acute ventilation impairment. However, other groups of patients and surgical procedures may benefit from this intraoperative ventilation mode.

NIMV was also described by a Japanese group for patients submitted to craniotomy for cerebral mapping.16 NIMV allowed for a sufficient anesthetic depth during bone opening and closure, total awareness during mapping, smooth transition between anesthesia and consciousness, suitable ventilation and immobility with comfort for the patient.

NIMV has been well documented in COPD during periods of acute exacerbations, reducing the respiratory work and improving clinical results, however its benefit during the anesthetic-surgical procedure remains undefined.

**CONCLUSION**

This case and the others reported in literature have proven the simple and easy applicability of NIMV at intraoperative period. NIMV appears to be a useful intraoperative ventilation support in situations of chronic disease, such as advanced COPD, as well as in worsened chronic and acute situations. Other groups of patients have been reported and may benefit. The anesthesiologist must become familiar with the noninvasive method and together with the clinical team, evaluate which patients will truly benefit from this type of support.

**RESUMO**

O manuseio anestésico de pacientes com doença pulmonar obstrutiva crônica grave é extensamente discutido devido ao elevado número de complicações destes pacientes, quando submetidos a procedimentos cirúrgicos de médio e grande porte. O objetivo deste estudo foi relatar um caso de paciente idoso portador de doença pulmonar obstrutiva crônica grave e coronariopatia, submetido a artroplastia de quadril sob anestesia espinhal e suporte intra-operatório de ventilação mecânica não-invasiva – bilevel positive airway pressure. Paciente do sexo masculino, 81 anos, doença pulmonar obstrutiva crônica grave (GOLD 4), submetido à artroplastia de quadril devido à fratura de fêmur sob anestesia espinhal e suporte intra-operatório de ventilação mecânica não-invasiva – bilevel positive airway pressure, sob parâmetros de pressão expiratória de 7 cmH2O, pressão inspiratória 15 cmH2O e fluxo de O2 de 3 L/min. Apresentou um episódio de broncoespasmo, revertido farmacologicamente, sem apresentar complicações no pós-operatório. A combinação de técnica anestésica regional com ventilação mecânica não-invasiva é de fácil aplicação e pode ser útil no intra-operatório destes pacientes de alto risco anestésico. A interação entre a equipe clínica, cirúrgica e de anestesia propiciou benefícios e reduz a morbimortalidade associada a procedimentos de grande porte em pacientes graves.
