A NEW SPECIES OF AMEROSEIUS (ACARI: MESOSTIGMATA, AMEROSEIIDAE) FROM BRASIL

CARLOS H. W. FLECHTMANN 2
CARLOS A. H. FLECHTMANN 3

ABSTRACT

A new species in the genus Ameroseius, viz. dendrovagans, is described and figured. It was collected in bark beetle (Scolytidae, Coleoptera) galleries in Pinus sp. in Minas Gerais, Brasil.

INTRODUCTION

Representatives of the family Ameroseiidae Evans, 1963 are poorly known in South America. The present study seems to be the first report on the presence of Ameroseius in Brasil. Also, emphasis on the biological control of injurious insects demands the identification of all their biological associates by the economic workers.

Ameroseius dendrovagans, sp. n.

Female: Dorsal shield entire, covering idiosoma entirely and overhanging the gnathosoma. This shield is brownish, ornamented with strong ridges forming a reticulate pattern and dimples; it bears 28 pairs of setae; these are mostly sickle-shaped, with rows of short pectinations. Some setae long, but the longest not reaching half of body width. Tectum broadly triangular, pointed anteriorly. Corniculi robust, trifid. Palpal apotele bifid. Fixed digit of chelicera with three proximal teeth. Tritosternum with a long base; laciniae short. Sternal shield bears 2 pairs of sternal setae; provided with line ornamentations. Sternal setae III situated on separate shields behind the posterolateral angulations of sternal shield. Metasternal setae on the cuticle. Genital shield with 1 pair of setae; with line ornamentations except for anterior flaps, whose anterior margin is not always clearly visible. Two pairs of pore-like structures are situated on the cuticle near the ventro-lateral margin of the genital shield. Peritremes long, extending anteriorly to coxae I. Ventro-anel shield elliptic, as figured. All legs with ambulacra.

Dimensions: length of dorsal shield 418 μm; greatest width 273 μm. Measurements of additional 5 females: 391 x 255; 432 x 289; 425 x 269; 381 x 241; 421 x 269 μm.

Male: Dorsal shield with the same general features as in females. Sterno genital shield with 5 pairs of setae; genital opening in an anterior invagination, preterminal; well separated from the ventro-anel shield. Fixed digit of chelicera with three proximal teeth; movable digit with a spermatodactyl.

Dimensions (of 2 specimens): length of dorsal shield 302 μm; greatest width 187 μm.

1. Supported, partially, by Conselho Nacional de Desenvolvimento Científico e Tecnológico, CNPq, Brasil.
3. Student, fellow of Instituto de Pesquisas e Estudos Florestais, SP, Brasil.
Ameroseius dendrovgans, sp. n. 1. Dorsal shield of female. 2. Ventral aspect of female. 3. Ventral aspect of male.
Ameroseius dendrovagans, sp. n. 4. Hypostome, ventral. 5. Tectum. 6-7. Chelicera.
Derivation of the name: from dendron (Greek = tree) + vagans (Latin = wandering on).

Diagnosis: *Ameroseius dendrovagans* is close to *A. corniculus* Karg, 1957, *A. imparsetosus* Westerboer, 1963 and *A. cavernosus* Westerboer, 1963. It is readily separated from *A. corniculus* by its spiniform i₁ setae (bushy in *corniculus*); from *imparsetosus* by the shorter i₅ setae (longer than half of body width in *imparsetosus*, shorter in *dendrovagans*); and from *cavernosus* by the structure of the dorsal setae (slender, almost needlelike in *cavernosus*; robust in *dendrovagans*).
