ABSTRACT
Objective: to evaluate the sexual function of Italian and Brazilian nursing students using the Female Sexual Function Index (FSFI), to estimate the prevalence of sexual dysfunctions and related factors. Method: this is a cross-sectional study involving 84 Brazilian and 128 Italian undergraduate. For the evaluation of sexual function, the Female Sexual Function Index (FSFI) questionnaire was used. Results: Italian women presented significantly higher sexual dysfunction index (n=78/60.9%) than the Brazilian women (n=32/38.1%) (p=0.00). Only the “desire” and “excitation” domains showed no difference between groups. Younger, single and without a steady relationship women had a higher rate of sexual dysfunction (p<0.05). Conclusion: the high rate of sexual dysfunction in a young public suggests the need for more research to increase knowledge about the influence of psychosocial and related factors on female sexual function, directing care towards the promotion of sexual and reproductive health.

RESUMO
Objetivo: avaliar a função sexual de acadêmicas de enfermagem italianas e brasileiras utilizando o Female Sexual Function Index (FSFI), estimar a prevalência das disfunções sexuais e os fatores relacionados. Método: estudo transversal, o qual participaram 212 universitárias, sendo 84 brasileiras e 128 italianas. Para a avaliação da função sexual, empregou-se o questionário Female Sexual Function Index (FSFI). Resultados: As italianas apresentaram índice de disfunção sexual significativamente superior (n=78/60,9%) do que as brasileiras (n=32/38,1%) (p=0,00). Apenas os domínios “desejo” e “excitação” não apresentaram diferença entre os grupos. As mulheres mais jovens, solteiras e sem relacionamento estável apresentaram índice de disfunção sexual maior (p<0,05). Conclusão: o elevado índice de disfunção sexual em um público tão jovem sugere a necessidade da realização de mais investigações que incrementem o conhecimento sobre a influência dos fatores psicossociais e relacionais na função sexual feminina, direcionando o cuidado para a promoção da saúde sexual e reprodutiva.

INTRODUCTION
The proper sexual function is an important factor of satisfaction and general quality of life; even so, female sexual dysfunction remains highly prevalent at rates ranging from 20 to 91% (1-4). Despite the impact on women's lives, few are those who seek health services capable of relieving the difficulties they encounter (5).

Because of shame, frustration or failures of subprofessional treatment, only a fraction of women have the initiative to talk about their sexual problems (6). In this regard, the World Health Organization (WHO) recognizes sexual dysfunction as a public health problem and recommends its investigation because it causes important changes in the quality of life (7).

Under different approaches and in various areas of knowledge, the topic of sexuality has attracted attention, being investigated in different groups. In the University, there are still few studies that evaluate the sexual function, however, the investigations already carried out indicate a wide range of prevalence in this population, with rates ranging from 25% to 91% (8-10).

Based on the initiative of the Núcleo de Estudo e Pesquisa em Promoção da Saúde Sexual e Reprodutiva (freely translated as Center of Study and Research in Promotion of Sexual and Reproductive Health/NEPPSS) in researching sexual dysfunctions in different populations and the informal verification of university complaints on the subject, the interest arose in identifying and evaluating this issue using a specific instrument called the Female Sexual Function Index (FSFI). Thus, the following question arose: Do Italian undergraduates have the same rate of sexual dysfunction as Brazilian undergraduates?

OBJECTIVE
To evaluate the sexual function of Italian and Brazilian nursing students using the Female Sexual Function Index (FSFI) and to compare the prevalence of sexual dysfunctions (dyspareunia, lack of desire, dissatisfaction and decrease of vaginal lubrication) between groups.

METHOD
Ethical aspects
The Universal Declaration on Bioethics and Human Rights was taken into account, respecting the aspects of autonomy, nonmaleficence, beneficence and justice. The study was authorized by the Ethics Committee of the Federal University of Ceará and La Sapienza University.

Design, place of study and period
This is an exploratory, analytical and cross-sectional study developed at two public universities. The population studied was composed of regularly enrolled nursing students in a Brazilian Federal University and an Italian Public University in the year 2013. The study was carried out from January 2013 to December 2015, with the data collection developed in the city of Rome-Italy and Fortaleza-Brazil, from February to December 2014.

Sample and criteria of exclusion and inclusion
To carry out this research, the probabilistic sampling was adopted. For the calculation, we considered the sample error of 5%, a prevalence of 27% of the phenomenon (8) for a population of 234 Italian nursing students and 324 Brazilian nurses regularly enrolled in 2013. It should be emphasized that the calculations were made isolated for each population, being a sample of 106 Brazilian and 135 Italian. Inclusion criteria were: Brazilian or Italian nationality, having a steady partner or being over 18 years old.

Due to the objectives of this study, 22 (20.8%) Brazilian women and seven (5.2%) Italian women were excluded from the analysis, making a sample of 212 academics, 84 Brazilian and 128 Italian.

Study protocol
Data collection was developed in the city of Rome-Italy and Fortaleza-Brazil through the Female Sexual Function Index (FSFI) and a form with socio-demographic and obstetric-gynecological variables. The FSFI is a questionnaire originally produced in English (9) and already validated into Portuguese (9) and Italian (10). It is specific and multidimensional, to evaluate the female sexual response, accessing its domains. The questionnaire consists of 19 questions, which report on five domains of sexual response: subjective desire/stimulation, lubrication, orgasm, satisfaction, and pain/discomfort. Individual scores are obtained by summing the items that comprise each domain (simple score), which are multiplied by the factor of that domain and provide the weighted score. The final score (total score: minimum of 2 and maximum of 36) is obtained by the sum of the weighted scores of each domain, and the higher the score the better the sexual function (9). After the signature of the Consent Term and other procedures of submission by the coordinators of the courses the procedure was approved by the Ethics Committee. The operation of the data collection took place as follows: 1º Stage: the students of each year in a group were clarified on the existence of the research, then they were invited to participate in the study, as the filling of the scale, and the socio-demographic and obstetric-gynecological form could be answered anywhere they trust or feel comfortable or via the internet. At the moment, the Informed Consent was also read, clarifying possible doubts.

Stage 2: After the signature and delivery of the term, the students answered the scale, and the socio-demographic and
gynecological-obstetrical form, via electronic, in their place of preference.

A participant who scored less than or equal to 26\(^{12}\) was considered a cutoff point for sexual dysfunction. All the instruments were made available in the online format through the Google Docs application to avoid possible biases, because of intimidation or shame.

**Analysis of results and statistics**

Data analysis was performed using Statistical Package for Social Sciences (SPSS), version 20 for Windows. First, the Kolmogorov-Smirnov test was applied in order to verify if the continuous variables had a normal distribution. Pearson's \(\chi^2\) was used to compare the nominal variables between the groups; and for the continuous variables the Mann-Whitney U test, due to the abnormal distribution of the data. Continuous variables were described on average and 95% confidence interval (95% CI). Pearson’s \(\chi^2\) was used to verify the association between the dependent variable of the study (sexual dysfunction) and the independent variables (socio-demographic data, personal and obstetrical history, and sexual history). To analyze the strength of the association, we used the Odds Ratio (OR) with a 95% Confidence Interval (95% CI).

**RESULTS**

The age bracket of undergraduates ranged between 18 and 39 years old. The Brazilian women were older and had lower family incomes. The Italians, on the other hand, had their menarche and age of sexual debut earlier (\(p<0.05\)) (Table 1).

Overall, both Brazilian and Italian women had a mean FSFI score of less than 26, however, the Brazilian sexual function was statistically better (BRA: \(M = 25.3\) 95% CI: 23.5-27.2/ ITA: \(M = 21.7\) 95% CI: 20.3-23.1) (\(p = 0.00\)). When analyzed separately, only the “desire” and “excituation” domains showed no difference between the groups (Figure 1).

When analyzed by percentage, the Italians presented more dysfunction (\(n=78/60.9\%\)) than the Brazilian ones (\(n=32/38.1\%\) \((p=0.00)\). The domain with the lowest scores for Brazilian women was “desire” (\(M=3.6\)) and for Italian women it was “orgasm” (\(M=3.1\)). The domain with the highest scores were “lubrication” (\(M=4.6\)) and “excitation” (\(M=3.8\)) for Brazilian and Italian, respectively.

In order to evaluate the factors related to the presence of dysfunction, the sample was divided into two groups: women without (\(n=103/48.6\%\)) and with dysfunction (\(n=109/51.4\%\)). Younger, single and without a steady relationship women had a higher rate of sexual dysfunction (\(p<0.05\)) (Table 2).

Figure 1 – Comparison of Female Sexual Function Index (desire, excitement, lubrication, orgasm, satisfaction and pain) domains between Brazilian and Italian women
DISCUSSION

Although the epidemiological data on sexual dysfunction are widely known worldwide, their values among undergraduates are still insufficient, with unusual investigations evaluating sexuality in undergraduates in Brazil and Italy. The young and vibrant public of undergraduates is concentrated, which most of the time does not have pathologies or signs and symptoms that have a negative impact on quality of life and sexuality.13-14

Although the sample had these characteristics, we found high rates (51.4%) of sexual dysfunction (FSFI total scores below 26). When compared to studies conducted specifically with undergraduates, Brazilian women presented the lowest percentages (38.1%), followed by African women (47% to 53.3%).6-7 The Italians presented percentages for the dysfunction, lower only to the Iranian ones (91%), which reinforces the influence of sociocultural factors on sexuality.

Despite the exhaustive search in the literature, no study was conducted to evaluate the presence of female sexual dysfunctions with nursing students using the FSFI, which is the appropriate instrument to evaluate the risk of sexual dysfunction. However, a study carried out with the objective of evaluating the sexual function of nursing undergraduates used the Female Sexual Function Index (FSFI) as an instrument, in which 28.4% of the students presented unfavorable and bad sexual performance patterns.15

The prevalence of sexual dysfunction in general populations using FSFI varies widely. In women under 59 years old and with no underlying diseases, prevalence was 43% among American women and 52.8% among Egyptian women.16 In Hong Kong, the incidence is 37.9% of sexual dysfunction among young and middle-aged married women.17 Meanwhile, an internet survey reported a 43.1% incidence of sexual dysfunction among Korean women under the age of 40.18

It is observed that the prevalence of sexual dysfunctions among the students here was high, when compared with other investigations with non-university women present in the literature, suggesting that despite their degree of knowledge regarding physiology, female anatomy and human sexuality, this population has difficulty in fully and effectively exercising their own sexuality.

It should be noted that prevalence data for sexual dysfunctions, in general, are highly diverse due to the existence of different classificatory systems, methods of evaluation and the population groups in these studies.19

In relation to “excitation”, “lubrication”, “orgasm”, “satisfaction” and “pain”, the data here presented confirms with other studies that, when sexual dysfunctions were evaluated it was found that “orgasm” was the most affected domain (55%), followed by “excitation” (40%), “desire” (39%) and “pain” (31%). “Orgasm” and “desire” were also identified as the main domains affected in other studies.20

In this study, variables, age, marital status and steady relationship showed significant relationships with the presence or absence of sexual dysfunction. Age was a risk factor especially among younger undergraduates. On the other hand, a previous study outlined the sexual profile of the Brazilian population and identified that older individuals reported greater dissatisfaction with their quality of sexual life.22 Among the 100 women attending a urology service in São Paulo, age was negatively correlated (p<0.001) with the “satisfaction” and “desire” domains (p=0.046), and the overall FSFI score (p=0.044).10 Such studies reinforce the assumption that as women age, the higher the possibility of sexual dysfunction due to vaginal atrophy and its consequences.22

On the other hand, other researchers point out that the prevalence of sexual dysfunction may be higher in single and under 20-year-old women due to dyspareunia, which is higher among younger women.24 A study that traced the sexual profile of the Brazilian population in seven cities in the country, said that age, marital status and schooling have long been known to influence the prevalence rates of sexual disorders.25 The results of the present investigation confirm these findings.

It is also worth noting the significant correlation of marital status with the presence or absence of sexual dysfunction. A similar result was found in a study that evaluated sexual dysfunction according to the relationship status (single, steady and married partnership) in young women (20-29 years) through an online survey.26 In this study, single women presented a significantly higher prevalence of problems in the “lubrication” (M=3.38, 45.3%), “orgasm” (M=3.01, 53.1%), “satisfaction” (M=2.82, 67.2%) and “pain” (M=3.06, 50%), as well as in the Total Female Sexual Function Index (M=19.43, 60.9%), in comparison with the other groups (steady and married partnership).26

These findings confirm the importance of the sexual partner in the female sexual performance and of the marital relationships in the satisfactory sexual response.26

Study limitations

The results of this study should be interpreted in light of its limitations. Sexual dysfunction was measured only by self-report and online, not allowing the university to direct the researcher to any questioning, if necessary. Most of the studies only presented data on the incidence of sexual dysfunction, but did not present the specific means of each domain, which compromised the more detailed analysis. It is also worth noting that the absence of a specific clinical diagnosis, which evaluates the organic conditions of the participants involved, that may be influencing the sexual function, may be relevant. Another limitation is that the study applied only the FSFI without associating other tools of clinical evaluation so that it was possible to infer some factor associated with sexual dysfunction.

Contributions to the area of nursing, health or public policy

The study brings as contribution the evaluation of sexual dysfunction, among undergraduates, little investigated in this aspect. The data revealed a surprising rate of dysfunction among undergraduates, which needs to be better investigated, especially as to the type and quality of the sentimental relationships in which they are inserted. In the society in which we live, more sentimental relationships are more fleeting with less commitment and intimacy with the partner. Such factors...
may be negatively influencing the promotion of sexual dys-
function in this population.

**CONCLUSION**

The high prevalence of sexual dysfunction evidenced in
this study legitimates the relevance of the subject. From the
FSFI scores, it was possible to verify which students have sexu-
al dysfunctions or a greater chance of developing them.
The findings of this study should be analyzed with caution,
since the sample was not representative of all geographic re-
gions of the countries involved in the study, and their data
cannot be generalized. However, the high incidence of sex-
ual dysfunction in such a young public suggests the need for
further research to increase knowledge about the influence of
psychosocial and relational factors on female sexual function,
directing care towards the promotion of sexual and reproduc-
itive health. A priori, younger women should be more fit and
satisfied with their sexual function, but that was not what the
study revealed. Among younger women, sociocultural factors
may be influencing more than purely biological factors.
