Evaluation of the handwashing technique held by students from the nursing graduation course*

Carla Cristiane Paz Felix¹, Ana Maria Kazue Miyadahira²

ABSTRACT
The purpose of this study was to compare the execution and verify the compliance with the handwashing techniques by students in an undergraduate Nursing course. The study was performed with 113 students enrolled in internship programs in healthcare institutions in the city of São Paulo. Data collection occurred through direct observation, using a check-list instrument with the steps of the technique. Students in their 2nd and 3rd year had better results in most steps of the technique, with a statistically significant difference when compared to the 4th year. Compliance with the steps of the technique by the students was very low, since their compliance with half the handwashing steps was lower than 50%. The average amount of students who executed all the steps of the technique correctly was very low, 8.8%. The observed students did not execute the handwashing techniques according to the recommendations.

RESUMO
O objetivo deste estudo foi comparar a execução e verificar a adesão à técnica de lavagem das mãos por alunos de um Curso de Graduação em Enfermagem. A pesquisa foi realizada com 113 alunos que estavam cumprindo estágio em instituições de saúde do município de São Paulo. Os dados foram coletados por observação direta utilizando um instrumento em forma de check-list com os passos da técnica. Os alunos do 2º e 3º ano obtiveram melhor desempenho na maioria dos passos na execução da técnica, com diferença estatisticamente significante, quando comparados ao 4º ano. A adesão aos passos da técnica pelos alunos foi muito baixa, pois apresentaram adesão menor que 50% em metade dos passos. A média de alunos que executou todos os passos da técnica corretamente foi muito baixa, 8,8%. Os alunos observados não realizaram a técnica de lavagem das mãos conforme recomendado.

INTRODUCTION

Hospital infections happen for many reasons and a number of mechanisms favor their occurrence. One of them is microorganism transmission by health professionals, who act as direct or indirect vectors in the transmission of pathogenic microorganisms to vulnerable patients. It is believed that one third of these infections can be prevented with infection control measures, one of which is adequate hand hygiene(2).

Hand washing is the most efficient and economical method to prevent nosocomial infections; and this is a well known fact throughout the world(3-6). After all, hands are the main transmission means for hospital infections and their washing should be conducted before and after any patient care procedure(5). The importance of this practice was also recognized by the Health Ministry when it included recommendations for hand hygiene in regulation 2616/98, May 12th, 1998(8).

In 1989, the Brazilian Health Ministry edited the Hand washing manual, aiming to standardize this technique in Brazilian health units, offering health professionals with technical substance related to standards and procedures to support hand washing, ANVISA (The National Health Surveillance Agency) launched the Hand washing – A small gesture, a big attitude campaign on May 15th, which is the National Day for Hospital Infection Control(9).

Although acknowledged as the most important preventive measure to reduce microorganism transmission by contact, many studies show that health professionals’ support for hand hygiene practice is very unsatisfactory(1,10-11).

The teaching-learning process of the techniques in the Nursing undergraduate course at the University of São Paulo School of Nursing (EEUSP) generally starts with an exposition class, where the student gets to know the scientific principles of a chosen nursing technique and the steps that should be followed. Afterwards, there is a technical demonstration in a laboratory, conducted by a professor or nurse. Following that, students are asked to perform the technique and the professor or instructor makes corrections when necessary. Finally, the students perform the technique in direct patient care, in other words, in real conditions(1,10-11).

At EEUSP, the hand washing technique is one of the first procedures students learn, during a theoretical class with text discussion, conducted by the instructor. Shortly after, the student is sent to the Nursing Procedures Laboratory, where the technique is performed by the student and the instructor or nurse makes the necessary corrections.

Knowing the importance of hand washing for health professionals’ practice and our responsibility in training our students, our future professionals, we proposed this study to evaluate nursing students’ performance when performing hand washing in the different periods of their undergraduate program.

OBJECTIVE

The purpose of this study was to compare the execution and verify compliance with the hand washing technique by students in the second, third and fourth periods of an undergraduate nursing course.

METHOD

This investigation is a cross-sectional comparative quantitative non-experimental study.

The sample comprised students from the EEUSP undergraduate nursing course, in the 2nd, 3rd and 4th periods, in 2006, who agreed to participate in the study.

At EEUSP, the hand washing technique is taught when the students are in the second semester of the undergraduate nursing course, before they start any internship. Moreover, during the whole course, the students have classes about a number of nursing procedures and hand washing is also addressed as a mandatory technique before and after any procedure.

Data collection was performed from June 19th until November 17th, 2006, during the students’ internship in a secondary-level teaching hospital and in Basic Health Units (BHUs) in the city of São Paulo, which consisted of technical observation of the students’ hand washing during their internship, according to the availability of the researcher. For each student, only one observation was conducted. In the period of July until September there was no data collection, since the students were not going through any internship programs.

A tool was designed with the steps for hand washing in the form of a check list, based on the Health Ministry recommendations(8). Two nurses helped the researcher during the data collection stage. These nurses received proper training in order to deeply know the check list, as well as its use during the collection. The students’ observation was conducted, simultaneously, by two people, the researcher and one of the nurses.

The ethical norms were followed and the project was approved by the research ethics committee and the EEUSP research committee (File #512/05).

The data was stored in a database designed using Microsoft Excel® and later transferred to the Statistical Pack-
age for Social Sciences (SPSS)® 10.0 for Windows®. The analysis was conducted by means of descriptive and inferential statistics, using the following tests: Pearson’s Chi-Square test, Fisher’s Exact test, Kolmogorov-Smirnov, Mann-Whitney and the non-parametric Kruskal-Wallis test.

RESULTS AND DISCUSSION

In total, 113 students, from the 2nd, 3rd and 4th years were observed, including 34, 42, and 37 students, respectively. The sample comprised 44.1% of the total number of students enrolled in the 2nd year, 51.2% of third-year students and 48.0% of fourth-year students. Data will be presented in a descriptive way, by charts or graphs.

This study concluded that 50% of the students carried out the hand washing procedure before and after conducting a procedure, in other words, complying with the recommendations by the Brazilian Health Ministry and USA CDC, i.e. 42.4% of the students washed hands only after procedures and 6.5% of the total carried out the technique only before conducting any procedure. There was a statistically significant association, p=0.001, among the different course years, measured by Fisher’s exact test, and this association happened between the 2nd and 4th years and between the 3rd and 4th years. In both cases, the proportion of fourth-year students conducting the steps before and after the procedure is lower when compared to the 2nd and 3rd years.

The proportion of fourth-year students who conducted the steps before and after the procedure was very low, 12.5%, when compared to the second and third years, with 82.1% and 59.4%, respectively. It was observed that compliance with this item diminished as students advanced in the course.

*To determine if there was a significant statistical difference among students of different course years in the items that compose the hand washing technique, Pearson’s chi-square test was used.

The data in Table 1 shows that most sample students (64.6%) did not remove their adornments (watch, bracelets or rings) before washing their hands. There was a significant statistical difference between the years, and they happened between the 2nd and 3rd years and between the 3rd and 4th years. The third year presented a better performance in comparison to the 2nd and 4th years. Between the 2nd and the 4th years, there was no significant statistical difference.

A study about evaluating the health professional’s hand washing technique concluded that 84.0% of the observed health professionals did not remove their jewelry when washing their hands (13).
Another study performed with 50 nurses working in surgical-medical units showed that skin under the rings is much more colonized by bacteria when compared to finger skin without this adornment. In this study, it was concluded that 40.0% of the nurses carried gram-negative bacillus, for example Klebsiella and Acinetobacter, in the skin under their rings and that these professionals certainly carried these microorganisms for months(14). In spite of this data, it is still unknown if there is a direct relation between wearing jewelry and a raise in pathogen transmission(2).

Students reported an average of 33.6% when it came to washing fingernails, with the 2nd and 3rd years presenting a small difference, 47.1% and 41.5% respectively, and a large difference in relation to the fourth year, which scored much lower than the others (13.5%).

Some studies documented that subungal areas of the hand have a high concentration of bacteria, mostly Staphylococcus sp coagulase-negative, Pseudomonas sp and Corynebacterium spp (15). The study about the use of antimicrobial soap or gel alcohol in hand hygiene concluded that there is frequently a substantial number of pathogens in subungal spaces, even after careful hand washing, with the use of surgical brushes(16).

A total of 58.6% of the students used a paper towel to close the faucet. The 4th year presented a big difference in relation to the other years, 82.9%. The 2nd and 3rd years presented values of 41.2% and 52.4%, respectively. The Brazilian Health (5) and the USA CDC(2) recommend the use of the paper towel that was used to dry the hands as a barrier to close the faucet, avoiding hand recontamination.

Studies in an IC unit evaluated the health professional’s compliance with the hand washing technique. In a first moment, the professionals were observed and it was noted that only 5% of them closed the faucet without contaminating their hands in a total of 525 observations. In a later moment, educational programs were conducted and it was noted that the number of professionals who did not contaminate their hands rose to 100% in a total of 355 observations(17).

The average number of students who conducted all technique steps correctly was very low, only 8.8%, and none of the students from the fourth year conducted the hand washing technique with all correct steps, as shown in Figure 1. The 2nd year presented the best rate 17.6% and the 3rd year, 9.5% (Figure 1).

![ALL CORRECT STEPS](image)

**Figure 1** - Proportion of students who conducted the steps correctly - São Paulo - 2007

Studies about the health professionals’ hand washing technique showed similar results, with only 14% of the evaluated health professionals complying with all of the technique steps correctly(19).

Generally, the second and third years presented a better performance of the hand washing technique, with significant statistical differences when compared to the fourth year.

When analyzing the data, an attempt was made to understand why the fourth year had a worse performance when it came to the hand washing technique. We believe this may have happened because there was a large period of time since they had the classes and demonstrations on the Nursing Laboratory. Another factor that may have influenced the outcome is that these students are in teaching institutions’ internships for longer. Many articles evidence the low compliance with the hand washing technique by health professionals, sometimes related to their beliefs and myths(18), and maybe the students were influenced by this organizational behavior.

Another reason would be the fact that the fourth year students have a higher freedom to execute their internship duties, since their internships are not supervised full time, as is the case with the second and third years, which have more direct professor/nurse supervision.
CONCLUSIONS

As for the comparison among the groups of students from the different years in relation to each step of the hand washing technique, it was concluded that the students from the second and third years presented a better performance, with significant statistical differences, when compared to the fourth-year students, and the students’ compliance rate to the steps of the hand washing technique was low throughout all years.

The percentage of students that performed all of the hand washing technique steps correctly was very low (8.8%); 17.6% for second-year students, 9.5% for third-year students and none for the fourth year.

Although the sample for this study was limited, the results show the need to invest in training strategies to raise student compliance with the hand washing technique, emphasizing the importance of the hand washing act for care service delivery.

1.0 – Student identification

Student name: _________________________________________________________ Date: ___/___/____ Age: ____ years

Gender: ( ) F ( ) M Year: 2nd ( ) 3rd ( ) 4th ( ) Unit where the student was observed ______________________________

Moment/situations in which the student washed his/her hands:

**Personal hygiene:**

A) When entering the unit

**To perform non-invasive care:**

B) Before preparing the medication.

C) After preparing the medication.

D) Before making a physical examination.

E) After making a physical examination.

F) Before cleaning and changing the patients’ clothes.

G) After cleaning and changing the patients’ clothes.

H) After making the bed.

I) Before performing a different activity on the same patient.

J) Before handling material and equipment.

L) After handling material and equipment.

**Before invasive procedures:**

M) Before a venous puncture.

N) After a venous puncture.

O) Before administering parenteral medication.

P) After administering parenteral medication.

Q) Before intravesical catheterization.

R) Before intravesical catheterization.

S) Before making a wound dressing.

T) After making a wound dressing.

U) Before performing tracheal aspiration.

V) After performing tracheal aspiration.

X) Before performing blood glucose measurements.

Z) After performing blood glucose measurements.
