SUMMARY

From January 1984 to May 1994, 17 of 239 children under 15 years old stung by Tityus serrulatus (15.1%) or Tityus bahiensis (84.9%) presented severe envenoming. Of these 17 patients (1-11 years old; median=2 yr) 14 were stung by T. serrulatus and three by T. bahiensis. All of them received scorpion antivenom i.v. at times ranging from 45 min. to 5 h after the accident (median=2 h). On admission, the main clinical manifestations and laboratory and electrocardiographic changes were: vomiting (17), diaphoresis (15), tachycardia (14), prostration (10), tachypnea (8), arterial hypertension (7), arterial hypotension (5), tremors (5), hypothermia (4), hyperglycemia (17), leukocytosis (16/16), hypokalemia (13/17), increased CK-MB enzyme activity (>6% of the total CK, 11/12), hyperamylasemia (11/14), sinusal tachycardia (16/17) and a myocardial infarction-like pattern (11/17). Six patients stung by T. serrulatus had depressed left ventricular systolic function assessed by means of echocardiography. Of these, five presented pulmonary edema and four had shock. A child aged two years old presented severe respiratory failure and died 65 h after being stung by T. serrulatus. Severe envenomations caused by T. serrulatus were 26.2 times more frequent than those caused by T. bahiensis (p<0.001).

KEYWORDS: Scorpion envenomation; Tityus serrulatus, Tityus bahiensis.

INTRODUCTION

Scorpion stings are common in tropical and subtropical regions, especially in the states of Minas Gerais, São Paulo, and Bahia. In Brazil, envenomation by scorpions is an important public health problem, especially in the state of São Paulo. In recent years, the incidence of accidents has increased, and the mortality rate is significant. Seventy-two deaths (88.8% of them involved children less than 15 years old) were reported to the Brazil Health Ministry from 1988 to 1989. T. serrulatus is the species responsible for most of the accidents in Brazil. However, in some regions, the frequency of accidents caused by T. bahiensis is high. Most patients stung by either T. serrulatus and T. bahiensis generally present only pain and paresthesia at the site of the sting. The percentage of severe envenomations (SE) caused by T. bahiensis and T. serrulatus is around 0.4% and 4.3%, respectively, with children being the most af-

fected. Only one death following a *T. bahiensis* sting has been reported in the Brazilian medical literature. In contrast, a mortality rate of around 1.0% in children and 0.28% for the total number of cases has been reported in *T. serrulatus* envenomations.

The present study compares the clinical manifestations, laboratory data and electrocardiographic (ECG) and echocardiographic (ECHO) changes of children with SE caused by *T. serrulatus* and *T. bahiensis*.

**RESULTS**

The frequency of severe envenomizing after *T. serrulatus* and *T. bahiensis* scorpion sting in the 239 children of this series is shown in Figure 1. Severe envenomizations caused by *T. serrulatus* were 26.2 times more frequent than those caused by *T. bahiensis* (p<0.001).

**Fig. 1.** Frequency of severe envenomizing (SE) following *T. serrulatus* and *T. bahiensis* scorpion sting in a series of 239 children. N = number of patients studied.

![Bar chart showing clinical features](image)

**Fig. 2.** Clinical features on admission presented by 17 children with severe envenomizing after *T. serrulatus* (Ts) and *T. bahiensis* (Tb) scorpion sting.

The clinical features, laboratory data and ECG changes presented on admission by the 17 patients with severe envenomizing after *T. serrulatus* and *T. bahiensis* scorpion sting are summarized in Figure 2 and Table 1.

The time course evolution of glycemia, kaliemia and leucocyte counts is shown in Figure 3. All of these parameters tended to return to normal values within 6 h to 18 h after the accident.

Legends: # = present, 0 = absent, * = death, Tb = *T. bahiensis*, Ts = *T. serrulatus*, # = time between the sting and the ECHO examination, DLVS = depressed left ventricular systolic function, PE = pulmonary edema, MI = myocardial infarction, CK-MB = creatine kinase isoenzyme MB, ET = endotracheal tube, MV = mechanical ventilation, nd = not done.

Two patients, one stung by *T. serrulatus* and the other by *T. bahiensis*, presented an urticarial rash after the AV administration, classified as mild early reactions. A child aged two years old was stung on the left foot by *T. serrulatus* and died 65 h after the accident. He presented vomiting, diaphoresis and somnolence immediately after the accident, and received scorpion AV (20 ml, i.v.) at his local first aid center 90 min later. Three hours after the accident he was admitted to the pediatric intensive care unit at UNICAMP. On initial examination, he presented prostration and was hypothermic, diaphoretic and pale and showed hypertonia of the upper limbs, coldness of the extremities, poor peripheral perfusion, a blood pressure difficult to measure, tachycardia and tachypnea. He was treated with parenteral administration of fluids, undergone hemodynamic monitoring (CVP, MAP, HR and ECG) without improvement of the clinical picture. Seven hours after admission, the child developed pulmonary edema and an ECHO examination revealed depressed left ventricular systolic function. The chest X-ray showed signs of bilateral lung edema without any enlargement of the heart (cardiothoracic ratio < 0.5). At this time, he was intubated and mechanical ventilation was started with 50-100% inspired oxygen concentration, 5-14 cm H₂O positive end-expiratory pressure and 25-54 cm H₂O peak inspiratory pressure. He developed progressive respiratory failure and died despite mechanical ventilation, dobutamine infusion and furosemide administration.
DISCUSSION

The venom from many species of scorpions causes the activation and delay of the inactivation of neuronal sodium channels. This effect can provoke a massive release of catecholamines and acetylcholine by postganglionic nerve endings. Such a release is directly related to the clinical instability observed in SE. A direct effect of scorpion venom on target organs can not, however, be excluded. In this study, both clinical and laboratory findings as well as the ECG and laboratory (hyperglycemia, leukocytosis, hypokalemia) changes were similar to those already described in the literature. Although the blood catecholamines levels were not measured, some of the clinical (tachycardia, arterial hypertension, diaphoresis, restlessness, cardiac arrhythmias, cardiac failure, pulmonary edema) and laboratory (hyperglycemia, leukocytosis, hypokalemia) features may be considered as indirect evidence of an increased sympathetic activity.

The treatment of SE can be divided into two steps. The first, and essential, is the adoption of vital supportive measures in the intensive care unit.

The second, the efficacy and benefit of which are controversial, is the use of AV. Although an adequate clinical study on the value of serotherapy remains to be performed, some studies advocate the administration of AV to all severely envenomed patients on admission. AV is the best treatment for experimental scorpion envenomation. High levels of T. serrulatus venom antigens have been found in the circulation of severely envenomed patients. In these individuals, scorpion AV quickly neutralized the circulating venom and decreased the pain and the vomiting, but was inefficient in reverting the cardiac manifestations. In addition, the frequency and the severity of early reactions to scorpion AV in children with adrenergic manifestations is low. Based on these findings, the frequency of early reactions to AV in this study was much lower than in children who received snake AV.

An autopsy was not performed in the child who died. However, his clinical, radiological and ECHO data as well as his parameters during mechanical ventilation, including arterial pO₂ levels, indicated a clinical outcome compatible with severe acute lung injury associated with cardiac failure.

Although T. serrulatus and T. bohienis venom have a similar LD₅₀ in mice, the present study has shown that in humans T. serrulatus provokes severe accidents more frequently and of greater severity than T. bohienis. Among several hypotheses to explain this observation there is the possibility that T. serrulatus could inject a higher quantity of venom.
RESUMO

Estudo comparativo do envenenamento escorpiônico grave em crianças provocado por Tityus bahiensis e Tityus serrulatus.

No período de janeiro de 1984 a maio de 1994, de 239 crianças com até 15 anos de idade, picadas por escorpiões pertencentes às espécies T. bahiensis (84,9%) e T. serrulatus (15,1%), 17 apresentaram envenenamento grave. Destes 17 pacientes, cuja idade variou de 1 a 11 anos (mediana=2anos), 14 foram picados por T. serrulatus e 3 por T. bahiensis. Todos receberam anti veneno escorpiônico i.v. entre 45 min. e 5 h após o acidente (mediana=2 horas). À admissão, as principais manifestações clínicas, alterações laboratoriais e eletrocardiográficas observadas foram: vômitos(17), sudorese profusa(15), taquicardia(14), prostração(10), taquipneia (8), derrame arterial(7), hipertensão arterial(5), tremores(5), hipotermia(4), hiperleucocitose(4), febre(4), febre(3), hipocalcemia(3), aumento do CK-MB (29%) e do CK(10%), hipertrigliceridemia(11/14), taquicardia(11/17) e padrão semelhante ao infarto do miocárdio(11/17). À ecocardiografia, observou-se depressão da função sistólica ventricular esquerda em 6 pacientes, todos picados por T. serrulatus. Destes, 5 apresentaram edema pulmonar e 4 choque. Uma criança de 2 anos de idade, picada por T. serrulatus, faleceu 65 horas após o acidente devido insuficiência respiratória grave. Concluiu-se que os acidentes graves determinados por T. serrulatus foram 26,2 vezes mais frequentes que os determinados por T. bahiensis (p<0,001).

ACKNOWLEDGEMENTS

We thank the medical and the nursing staff of the pediatric emergency and the intensive care units, of the Hospital das Clínicas, Universidade Estadual de Campinas (UNICAMP), for their dedication in the treatment of patients with scorpion envenomation. We also thank to Flavia S.F. Gellert and Stephen Hyslop for reviewing the English of the manuscript.
