SUMMARY

We present a case of histoplasmosis with multiple pulmonary nodules in a patient with a history of melanoma. This case closely simulated malignancy, including the presence of feeding vessel sign, which occurs in pulmonary metastasis. We emphasize the need to be aware of this infection in areas where histoplasmosis is endemic.

KEYWORDS: Histoplasmosis; Histoplasma capsulatum; Pulmonary nodules; Metastatic lesions.

INTRODUCTION

Classic histoplasmosis, a granulomatous disease caused by the dimorphic fungus Histoplasma capsulatum var. capsulatum (H. capsulatum), is endemic in certain areas of North and Latin America. Brazil is an area of higher prevalence of cases.

The vast majority of infections with H. capsulatum are completely asymptomatic or, at least, subclinical. The disease is resolved spontaneously over a period of 2-4 weeks. The roentgenographic signs are resolved completely in 2-4 months or leave calcified hilar and/or mediastinal lymph nodes or pulmonary histoplasmosmas.

On the other hand, histoplasmosis may mimic metastatic lesions by having similar radiographic findings when presenting the tendency to be peripheral on the lower lobes. The aim of this report is to present one of such case with feeding vessel sign that occurs in pulmonary metastasis in a patient with a history of previously diagnosed melanoma.

CASE REPORT

We present a 64-year-old asymptomatic woman with a history of a wide local excision of a superficial melanoma (Clark level II) eight years ago. During this time she showed no signs of recurrence upon periodic examinations. Presently, a chest x-ray revealed multiple pulmonary nodules in the right lower lobe. On physical examination, she appeared well. No lymphadenopathy was found. A high-resolution axial computed tomography (CT) scan with maximum intensively projection (MIP) technique that highlighted pulmonary nodules showed numerous small nodules in random distribution. The high-resolution coronal CT scan with MIP technique demonstrated a right lung nodule with feeding vessel sign, which occurs in pulmonary metastasis (Fig. 1 and 2). Histopathological examinations of lung biopsy specimens stained...
by hematoxylin and eosin (H&E) showed multiple small white nodules (0.5 - 1.0 cm), and tuberculoid granuloma with central caseous necrosis surrounded by fibrous connective tissue presenting giant cells (Fig. 3A and B). Replicate section stained by Gomori-Grocott methenamine silver (GMS) showed multiple small, round to oval yeasts of *H. capsulatum*. The patient was treated with itraconazole, 200 mg/day for one month, followed by 100 mg daily for six weeks. The antifungal treatment was suspended after six weeks according to the guideline 2007. In a recent follow-up she appeared to be in good clinical condition.

Finally, in a retrospective mycological evaluation the serologic (immunodiffusion) test for histoplasmosis was negative, and the epidemiologic history showed that the patient had cleaned out a bat-infested attic three years earlier.

**DISCUSSION**

Microconidia of *H. capsulatum* (2 to 5 µm) are small enough to be inhaled into the lungs during environmental disturbances. These primary infectious particles are observed in the mycelial form of the fungus, which finds a natural habitat in soil with high nitrogen content, such as areas contaminated with bat and chicken excrements. Prevention of histoplasmosis infections can often be accomplished by avoiding such areas. If this is not possible, any procedure that minimizes the production of aerosolized dust should be instituted. Especially given that after a heavy exposure, most infections are symptomatic and result in acute pulmonary histoplasmosis.

In this case, the patient was exposed to inoculum for a short period of time and developed mild clinical symptoms, and later, chest roentgenograms revealed some peripheral lung nodules, mimicking metastatic lesions. MACKIE *et al.* report a similar case, in which a patient with known metastatic melanoma who was presenting for restaging was initially considered to have widespread mediastinal and cervical metastasis on the bases of the imaging findings.

The incidence of melanoma has increased during the past several decades, and approximately 70% of new cases of melanoma are thin lesions. Patients with these lesions are generally considered to be at low risk for metastasis. However, it is well known that a portion of this group will eventually experience disease recurrence, which was suspected to occur in our case with a melanoma Clark level II history.

In conclusion, histoplasmosis as a self-limited disease in most patients continues to complicate the evaluation of pulmonary nodules and often leads to surgical resection. Exploration in patients with presumed pulmonary metastases from melanoma is justified to rule out benign disease. Ideally, samples of the lung lesions should be taken for culture. This procedure is not always possible, as in this case, because the tissue was immersed in formalin. Therefore, the pathologist, rather than microbiologist, must assume the responsibility for the identification of the infection agent by special tissue stain.

**RESUMO**

Histoplasmose apresentando múltiplos nódulos pulmonares. Um caso simulando características radiológicas de metástase pulmonar

Apresentamos caso de histoplasmose com múltiplos nódulos pulmonares em paciente com história de melanoma. Este caso simula malignidade, incluindo o sinal de vaso nutridor que ocorre na metástase pulmonar. Enfatizamos a necessidade de considerar esta infecção em áreas onde a histoplasmose é endémica.

The Library of the São Paulo Institute of Tropical Medicine (IMTSP Library) was created on January 15, 1959 in order to serve all those who are interested in tropical diseases. To reach this objective, we select and acquire by donation and / or exchange appropriate material to be used by researchers and we maintain interchange between Institutions thorough the Journal of the São Paulo Institute of Tropical Medicine, since the Library has no funds to build its own patrimony.

The IMTSP Library has a patrimony consisting of books, theses, annals of congresses, journals, and reference works.

The collection fo journals existing in the Library can be verified through the USP – Bibliographic Database – OPAC – DEDALUS  http://dedalus.usp.br:4500/ALEPH/eng/USP/USP/DEDALUS/start of the USP network.
