ABSTRACT

Objective: this study investigates the relationship between problematic drinking, gender, age, marijuana consumption, driving under the influence of alcohol and riding with an alcohol intoxicated driver among university students in Barbados.

Method: a cross-sectional survey was used to collect data from 371 students, the majority of whom were female (73.6%) and between the ages of 18 and 21 (60.6%).

Results: the majority of participants (81.1%) consumed alcohol in the preceding 12 months and 17.2% met the criteria for problematic drinking based on their Alcohol Use Disorders Identification Test score. A significant relationship was uncovered between problematic drinking and student gender, driving under the influence alcohol, riding with an alcohol intoxicated driver and marijuana consumption.

Conclusion: further research using a representative sample should be conducted to determine if the findings hold true for the wider student population. Nevertheless, the study highlights the presence of problematic drinking among the students and therefore initiatives should be implemented to reduce and eliminate its occurrence.

BEBIDAS PERIGOSAS E SEUS CORRELATOS ENTRE UNIVERSITÁRIOS DE BARBADOS

RESUMO

Objetivo: este estudo investiga a relação entre o uso problemático de bebidas, sexo, idade, consumo de maconha, dirigir sob a influência de álcool e andar com motorista alcoolizado entre estudantes universitários em Barbados.

Método: utilizou-se um levantamento transversal para coleta de dados de 371 estudantes, sendo a maioria do sexo feminino (73,6%) e com idade entre 18 e 21 anos (60,6%).

Resultados: a maioria dos participantes (81,1%) consumiu álcool nos últimos 12 meses e 17,2% preencheram os critérios para uso problemático de bebidas com base na pontuação do Teste de Identificação dos Distúrbios do Uso de Álcool. Uma relação significativa foi descoberta entre o uso problemático bebidas e o gênero dos estudantes, dirigir sob a influência do álcool, andar com um motorista alcoolizado e consumir maconha.

Conclusão: mais pesquisas usando uma amostra representativa devem ser conduzidas para determinar se as descobertas são verdadeiras para a população estudantil mais abrangente. No entanto, o estudo destaca a presença de consumo de bebidas problemático entre os alunos e, portanto, iniciativas devem ser implementadas para reduzir e eliminar sua ocorrência.

BEBIDAS PELIGROSAS Y SUS CORRELATOS ENTRE UNIVERSITARIOS DE BARBADOS

RESUMEN

Objetivo: este estudio investiga la relación entre el uso problemático de bebidas, sexo, edad, consumo de marihuana, conducir bajo los efectos del alcohol y conducir con un conductor ebrio entre estudiantes universitarios en Barbados.

Método: se utilizó una encuesta transversal para recopilar los datos de 371 estudiantes, la mayoría de ellos mujeres (73,6%) y edades entre 18 y 21 años (60,6%).

Resultados: la mayoría de los participantes (81,1%) consumió alcohol en los últimos 12 meses y 17,2% cumplió con los criterios para el uso problemático de bebidas, según el puntaje del Test de Identificación de Trastornos por Consumo de Alcohol. Se descubrió una relación significativa entre el consumo problemático de bebidas y el género de los estudiantes, conducir bajo los efectos del alcohol, conducir con un conductor ebrio y consumir marihuana.

Conclusión: se debe realizar una investigación adicional con una muestra representativa para determinar si los hallazgos son ciertos para la población estudiantil en general. Sin embargo, el estudio destaca la presencia del consumo problemático de bebidas entre estudiantes y, por lo tanto, se deben implementar iniciativas para reducir y eliminar su ocurrencia.

INTRODUCTION

Hazardous drinking, sometimes referred to as problem drinking, is a public health issue and is particularly concerning given its associated harms and the popularity of alcohol consumption worldwide. Throughout this hemisphere, alcohol continues to be the most frequently consumed substance and Barbados is no exception, with approximately 75% of this country's general and secondary school populations reporting lifetime alcohol use. Local past year prevalence rates for these populations stand at around 55%. Alcohol use is also common among university and college students on the island. One local study found that 70.6% of students at tertiary level institutions (university, colleges and post-secondary schools) consumed low alcohol content beverages (beer, stout, etc.) to varying degrees. Medium (wine, liqueurs, etc.) and high (rum, vodka, brandy, etc.) alcohol content beverages were consumed by 65.1% and 54.1% of students respectively.

The international literature highlights the issue of hazardous alcohol use among university students across the globe. One study found high rates of alcohol use disorders and hazardous drinking among undergraduate students from seven universities across England. Three-fifths of the sample scored eight or above on the Alcohol Use Disorders Identification Test (AUDIT), thus testing positive for hazardous drinking. There were no significant differences between the AUDIT scores of males and females.

The AUDIT was also used to investigate alcohol consumption among university students in Malawi. Just under half of the participants (45.3%) in that study were considered problem drinkers as they received an AUDIT score of eight or above. Additionally, the researchers found a statistically significant difference in the AUDIT scores of males and females, with more males being classified as problem drinkers. Research conducted among Vietnamese medical students also found that males were more likely than females to be classified as problem drinkers. While 12.5% of participating medical students had an AUDIT score of eight or more, males were 14.3 times more likely than females to receive such a score.

Hazardous drinking has been associated with other dangerous behaviours. For instance, research conducted among Irish university students found that hazardous drinkers were more likely to smoke, use illicit drugs and engage in increased sexual activity.

Hazardous drinking has also been linked to driving under the influence (DUI) of alcohol. One group of researchers found the mean AUDIT score for drivers convicted of DUI alcohol to be greater than eight (M=11.1, SD=5.9), indicating hazardous use, while the mean score for those without such a conviction was less than eight (M=7.4, SD=5.4). Similarly, in another study, AUDIT scores were found to increase as the number of DUI convictions a person received increased. Persons with one conviction had a mean score of less than eight while persons with two or more convictions had a mean score greater than eight, suggestive of hazardous use.

Hazardous alcohol use, as measured by the AUDIT, has also been identified as a risk factor for riding in a car operated by an alcohol intoxicated driver. Correspondingly, binge drinking, an indicator for hazardous alcohol use, has also been proven to be a predictor of riding with an alcohol impaired driver.

The issue of hazardous alcohol use and its association with DUI behaviours is of particular concern among university students, as young adults are the most at-risk group for DUI. Furthermore, motor vehicle accidents have been identified as the leading cause of death among persons ages 15 to 29 in Latin America and the Caribbean.

The aim of this study was to assess the hazardous use of alcohol among university students in Barbados and to determine its correlates. More specifically, the study sought to determine if hazardous alcohol use is related to gender, age, consumption of marijuana, consumption of marijuana...
and alcohol in one session (combined), DUI alcohol and being a passenger in a car operated by an alcohol intoxicated driver.

**METHOD**

This quantitative study was cross-sectional in design and utilized the survey method for data collection. The study's population was limited to undergraduate and post-graduate students, ages 18 to 29, enrolled in on-campus programmes at a university in Barbados. An online sample size calculator identified the minimum required sample size as 368.

A non-probability sample of 371 students was selected from within the classrooms of the university. To facilitate this process, lecturers were contacted and asked if they would be willing to have the questionnaire administered during their class time. A mutually convenient date and time for questionnaire distribution was established with those lecturers who consented.

Once in the classroom, potential participants were identified and provided (as a group) with a verbal description of the study. Those who agreed to participate were required to sign consent forms and were then provided with a copy of the questionnaire to complete immediately. This process took approximately 20 minutes. Students placed completed questionnaires in the envelope(s) provided as they exited the room.

A self-administered questionnaire was used to collect the data for this study. Participants were asked to provide their age and gender. In addition, they were asked about their past year use of alcohol, marijuana and alcohol and marijuana combined.

Persons who consumed alcohol in the preceding year were asked to complete the AUDIT to determine if they were hazardous drinkers. This 10-item scale was developed by the World Health Organization and identifies hazardous and harmful drinking patterns during the preceding 12 month period. It has high internal consistency and test-retest scores and correlates strongly with other measures used to evaluate hazardous alcohol consumption. Responses to each item are assigned a numerical score. Item scores are summed to provide a total score for interpretation. In accordance with interpretation instructions, persons receiving a score of eight or above were considered to have met the criteria for hazardous alcohol use and were therefore classified as “hazardous drinkers”. Those with scores of 7 or below were considered to be “non-hazardous drinkers”.

Past year alcohol users were also asked to indicate the number of times they had driven, or had been a passenger in a car driven by someone, under the influence of alcohol in the preceding 12 months. Possible responses included “Never”, “Once”, “2 times”, and up to “8 or more times”. For the purposes of analysis, the responses to these items were recoded into “Yes/No”.

The data for this study was collected as part of a wider research project which examined DUI among university students. As such, the questionnaire included additional items which evaluated hazardous marijuana use, DUI marijuana, DUI marijuana and alcohol combined, DUI within participants’ social networks and the perception of risk associated with DUI.

Data analysis was carried out using the Statistical Package for the Social Sciences (SPSS) version 21. Descriptive statistics were used to determine the sample’s demographic characteristics and the proportionate use of alcohol within the sample. Chi-square analyses and cross-tabulations were used to evaluate the relationship between AUDIT classification (hazardous/non-hazardous drinker) and participant age and gender. Chi-square analyses and cross-tabulations were also used to investigate the relationship between AUDIT classification and DUI alcohol in the past year, being a passenger with a driver who has been using alcohol in the past year, past year marijuana use and the combined use of alcohol and marijuana in the past year.
RESULTS

Sample demographics

Females accounted for 73.6% of the sample and males 26.4%. This a reflection of the sex ratio of students enrolled at the university. The majority of participants (60.6%) were in the 18 to 21 age group while fewer persons were in the 22-25 (31.0%) and 26-29 (8.4%) age categories.

Alcohol consumption & hazardous drinking

Most (81.1%) participants (80.6% of males and 81.3% of females) had consumed alcohol during the 12 months leading up to the survey. The mean AUDIT score was 4.4073, with a minimum of 0 and a maximum of 22. Based on their AUDIT scores, 17.2% of these persons met the criteria for hazardous drinking while 82.8% were non-hazardous.

Hazardous alcohol use & sample demographics

Participant gender was related to AUDIT classification (d.f.=1, $\chi^2=8.481$, $p<.05$). The percentage of males categorized as hazardous drinkers was greater than the percentage females receiving this classification (See Table 1). With regards to age, no relationship was found between this variable and AUDIT classification (See Table 1).

Hazardous alcohol use & driving under the influence of alcohol

Chi-square analysis revealed an association between AUDIT classification and DUI alcohol (d.f.=1, $\chi^2=14.286$, $p<.001$). Approximately three quarters (76.3%) of hazardous drinkers reported DUI alcohol at least once during the preceding 12 months. In contrast, only 41.4% of non-hazardous drinkers admitted doing so during the same time period.

AUDIT classification was also related to riding in a car operated by someone under the influence of alcohol during the past year (d.f.=1, $\chi^2=5.008$, $p<.05$). While 80.8% of hazardous drinkers reported engaging in this behaviour, only 64.8% of non-hazardous drinkers reported doing so (Table 2).

Hazardous alcohol use & marijuana use

There was an association between AUDIT classification and past year marijuana use (d.f.=1, \( c^2 =20.516 \), p<.001). The proportion of hazardous drinkers who used marijuana in the preceding 12 months was greater than the proportion of non-hazardous drinkers who had done so (Table 3). Likewise, the use of marijuana and alcohol in the same sitting (combined) during the past year was more common among hazardous drinkers (d.f.=1, \( c^2 =32.172 \), p<.001) (Table 3).

DISCUSSION

The past year prevalence rate for alcohol use was higher than that uncovered by previous local research (+~25%). This is not surprising as the previous research which generated prevalence rates focused on the general and secondary school populations. University students on the other hand, typically have higher rates of alcohol consumption which may be due in part to the social environment on campus, the ease with which alcohol can be obtained and increased autonomy from parents.17–19

In addition, there is also evidence which suggests that undergraduate students drink even more than their non-student peers.5, 17

The level of hazardous alcohol use within the sample is not alarmingly high when compared to that of international studies. On the contrary, it is notably lower than that uncovered in countries such as the United Kingdom and Malawi.5–6 Nevertheless, it highlights the fact that hazardous alcohol use exists among university students in Barbados, and therefore targeted interventions aimed at preventing and addressing this phenomenon should be developed and implemented. However, further research should first be conducted to ensure a full understanding of the issue and, by extension, guide their development.

The study also found that hazardous drinking among university students in Barbados is associated with gender and other risky behaviours such as DUI alcohol, riding with an alcohol intoxicated driver and using marijuana, both alone and in combination with alcohol. These findings
correspond with the international literature. Age was the only variable under investigation which was not related to hazardous drinking.

The fact that male students were more likely to be hazardous drinkers may be a byproduct of socialization as society is generally more accepting of such behaviour among males. Associated behaviours, for example, excessive alcohol consumption and binge drinking, are often considered as signs of masculinity. As such, young males are more likely to adopt these behaviours in an attempt to prove their machismo and maturity. Additionally, it is thought that males are greater risk takers than females and thus are more likely to engage in risky behaviours such as hazardous drinking. It is important to note that the presence of such gender differences may have important implications for selective and indicated prevention interventions, and should therefore be considered when such efforts are being designed and implemented.

The finding that hazardous drinking is related to DUI alcohol, riding with an alcohol intoxicated driver and marijuana use coincides with research which has shown an association between higher AUDIT scores and risk taking behaviour. Similarly, the findings are also consistent with research which has found a relationship between alcohol consumption patterns, particularly high rates of use and dependence, and behavioural risk taking. It is possible that hazardous alcohol consumption increases the risk for participating in other risky behaviours, due in part to the mere effects of intoxication.

The study relied on the use of a non-probability sampling method. This prevents the generalization of the findings to the wider university population as the sample was not representative. Furthermore, certain subject areas (e.g. psychology, social work) were overrepresented within the sample due to many lecturers’ unwillingness to facilitate the data collection process. This may have affected the results; however, it is not possible to determine if non-respondents from other subject areas may have differed in their responses.

The social desirability bias may have resulted in persons underreporting their drug use and DUI behaviours. Thus, the findings may not be an accurate reflection of what is happening within the target population. However, it is hoped that the anonymity afforded by the study, coupled with the guarantee of confidentiality, counteracted any potential impact which the social desirability bias may have had.

Similarly, the accuracy of participants’ responses, and by extension the study’s findings, may have inadvertently been reduced by the reliance on self-report data, as participants may have been unable to accurately recall the events under study.

CONCLUSION

This study provides insight into alcohol consumption by university students in Barbados and highlights the existence of hazardous drinking among the student body. It also reveals a number of risk taking behaviours which are associated with hazardous drinking. This information can be used to inform university policies as well as to guide the design and implementation of programmes and initiatives aimed at discouraging risky drinking practices, reducing high risk behaviours and promoting healthy lifestyles. In so doing, it must be remembered that universities do not exist in a vacuum but are part of the wider communities, cities and countries in which they are located. As such, any efforts should be multifaceted and should involve relevant organizations and businesses, including bars and nightclubs, as well as other government agencies and departments, for example the police, health services, the local drug council, etc. so as to increase their success.

As a consequence of this study’s limitations, it is recommended that further research using a probability sample be conducted to determine if the findings hold true for the wider student body. In addition, quantitative research on the topic can be complemented by qualitative studies of a similar nature which can provide useful context and a greater understanding of the problem.
