Cortex Moutan

Daodi medicinal material

ABSTRACT

To know more about the potential roles of endophytic fungi in the formation mechanism of Daodi medicinal material, diversity and communities of culturable endophytic fungi in three types of tree peonies were investigated. Endophytic fungi of three types of tree peonies were isolated and identified. The diversity was analyzed. Bayesian trees constructed by MrBayes 3.2.6 after phylogenetic analysis of the ITS sequences. The endophytic fungi potential for synthesis of natural products was assessed by means of detecting NRPS and PKS gene sequences. In total, 364 endophytic fungi isolates representing 26 genera were recovered from *Paeonia ostii* 'Feng Dan', *Paeonia ostii* 'Luoyang Feng Dan', and *Paeonia suffruticosa* 'Luoyang Hong'. More culturable endophytic fungi appeared in *P. suffruticosa* 'Luoyang Hong' (206) compared with *P. ostii* 'Feng Dan' (60) and *P. ostii* 'Luoyang Feng Dan' (98). The fungal community of *P. ostii* 'Feng Dan' had the highest richness and diversity. PKSs and NRPS detection rates of endophytic fungi from *P. ostii* 'Feng Dan' are both the highest among the three types of tree peonies. Results indicate that endophytic fungus is an important factor of Daodi Cortex Moutan forming, and endophytic fungi in peony are related to genuineness of Cortex Moutan.

Introduction

Some traditional Chinese medicinal materials that are produced in specific geographic regions with designated natural conditions and ecological environment, and widely recognized as having better beneficial clinical therapeutic effects are called Daodi medicinal materials or geoherbs.¹ As the essence of Chinese medicinal materials, Daodi medicinal materials have enjoyed a good reputation and have been playing an important role in treating disease and preserving health for thousands of years. From a biological point of view, heterogeneous individuals of the same species can be classified as either geoherbs or non-geoherbs, with their unique chemical constituents resulting from the interaction between minor polygenes and differential ecology.² For instance, *Paeonia suffruticosa* Andrews, commonly called the tree peony, belongs to the Ranunculaceae family. The root bark of *P. suffruticosa* is called Cortex Moutan, which is a famous Chinese medicinal material and widely used in traditional Chinese medicine. Cortex Moutan produced from *Paeonia ostii* 'Feng Dan' in Tongling city, located in Anhui Province is considered a Daodi medicinal material (also called geoherbs). However, Cortex Moutan, which produced from *P. ostii* 'Feng Dan' that were transplanted in other regions of China or from other peony varieties, are called non-Daodi medicinal material (also called non-geoherbs). In recent years, researchers have studied the formation mechanism of Daodi Cortex Moutan from the perspectives of processing technique, environmental conditions, geochemistry, rhizosphere soil microorganism, trace elements, metabolism in animals, and obtained a series of important achievements. But the dominant factors of Daodi Cortex Moutan forming are not yet clear, the formation mechanism of Cortex Moutan needs further research.

Endophytic fungi are a group of diverse, fungal microorganisms that spend the whole or part of their life cycle in living plant tissues without causing any noticeable symptom of disease.^{3,4} It is noteworthy that endophytic fungi are ubiquitous in plant species that exist on the earth, and the endophytic colonization differs from tissues to tissues.^{5,6} They play important roles in the process of host plant growth and systematic evolution. Studies have shown that endophytic fungi have the capability to produce many kinds of identical or similar biologically active constituents as their host plants. These active constituents include antineoplastic paclitaxel,⁷ camptothecin,⁸ deoxypodophyllotoxin,⁹ the hypericin, etc.¹⁰ Polyketide synthetases (PKS) and non-ribosomal peptide synthetases (NRPS) are multifunctional enzymes catalyzing the biosynthesis of structurally diverse bioactive natural products. Polyketides and non-ribosomal peptides have been immensely concerned over the past decades, and numbers of various novel polyketide and non-ribosomal peptide compounds have been found from endophytic fungi. The presence of PKS and NRPS in fungi suggest their potential in producing related compounds and guides in producing related natural products.^{11–13} Endophytic fungi are widely distributed in healthy plant tissues. In addition, endophytic fungi can produce secondary metabolites that are also biosynthesized by their host plants. Is there an interrelationship between endophytic fungi and the formation of Daodi medicinal material?

Is there a difference in diversity and communities of endophytic fungi between Daodi medicinal material and non-Daodi medicinal material?

In this study, with the aim to know more about the tree peony endophytic fungal diversity and find evidence for the potential roles of endophytic fungi in the formation mechanism of Daodi medicinal material, our objectives were therefore to (1) isolate and identify genetically and morphologically filamentous endophytic fungi of tree peonies from two different regions, (2) investigate the variation in the diversity and communities of the endophytic fungi population of tree peonies (geoherbs and non-geoherbs), (3) the potential of endophytic fungi in producing bioactive natural products was estimated based on the detection of PKS and non-ribosomal peptide synthetases (NRPS) genes.

Materials and methods

Plant sample collection

P. ostii 'Feng Dan' belongs to the section Moutan of the genus *Paeonia* and the family Paeoniaceae.¹⁴ Five-year-old *P. ostii* 'Feng Dan' plants, which were considered as the raw material of Daodi medicinal material, were collected from Phoenix Mountain Peony Garden, Tongling city, Anhui Province, China.

P. ostii 'Feng Dan' seedlings had grown in Anhui province for two years, and then the two-year-old seedlings have been transplanted in Luoyang city for three years. These five-year-old peony samples were collected from peony cultivation base of National Flower Park of China, Luoyang, Henan, China. In order to distinguish them from the above peony variety, we named them as *P. ostii* 'Luoyang Feng Dan'. In essence, *P. ostii* 'Luoyang Feng Dan' and *P. ostii* 'Feng Dan' are the same peony varieties, but their growing regions are different. *P. ostii* in Tongling city and Luoyang city were named after *P. ostii* 'Feng Dan' and *P. ostii* 'Luoyang Feng Dan' respectively in the following narrative.

P. suffruticosa 'Luoyang Hong', a typical purplish red-flowered cultivar of Chinese traditional *P. suffruticosa* cultivars, is particularly appreciated by Chinese. In our study, *P. suffruticosa* 'Luoyang Hong' was also collected in peony cultivation base of National Flower Park of China, Luoyang city, Henan Province, China. The three types of tree peonies were collected in October 2014. A total of 30 individuals of each kind of tree peonies were collected. All plant materials were immediately brought to the laboratory, stored at 4 °C in refrigerator and preprocessed within 24 h. The tree peonies endophytic fungi were isolated according to the surface sterilization method described by Li Peng et al.¹⁵

Isolation and identification of endophytic fungi

The endophytic fungi were incubated on potato dextrose agar (PDA: 200 g scrubbed and diced potatoes, 15 g dextrose, 20 g agar, and 1 L distilled water) plates at 25 °C in the dark until the colonies reached the rim of the dishes (9 cm in diameter). All fungi isolates were examined periodically, and were classified into morphotypes based on their growth rates and morphological and microscopic

characteristics (including shape of the mycelium, texture of the mycelium surface, production of spores (conidia, blastospores, sporangiospores or ascospores), color of the fungi, production of pigments and their diffusion into the medium). A total of 156 morphotypes were then identified based on the ITS sequence data. Mycelia of the fungal endophytes were ground completely with liquid nitrogen in a sterile mortar, and Genomic DNA extraction from all endophytic fungi was performed using a DN41 rapid DNA extraction kit (Aidlab Biotechnologies Co. Ltd., Beijing, PR China) following the manufacturer's recommendations for fungi. The internal transcribed spacer (ITS) region was amplified with universal primers ITS1(5'TCCTCGTTGGTGAAC CTGGG3') and ITS4(5'TCCTCCGGTTATTGATATGC3'). PCR mixture contained 12.5 µL 2× Taq PCR Master Mix (Taq DNA Polymerase, Buffer, MgCl₂ and deoxynucleotide triphosphates (dNTPs) were contained), 1 µL DNA sample, 1 µL of each primer and 9.5 µL double distilled water. The PCR reaction conditions were as follows: initial pre-heating at 94 °C for 3 min, 30 cycles of 94 °C for 30 s, 58 °C for 30 s, 72 °C for 30 s, and a final extension at 72 °C for 10 min. After amplification, the PCR products were analyzed by electrophoresis on a 1.2% agarose gel stained with ethidium bromide (0.5 ng/mL agarose) by stirring gently for 15 min; the products were then visualized under UV light. The PCR products were separated on 1% (w/v) agarose gel and purified using a DNA Gel Extraction Kit (AXYGEN, Suzhou, PR China). The resulting DNA was sequenced directly using the same primers (Beijing Honor Tech Co. Ltd., Beijing, PR China).

The ITS sequence data of the endophytic fungi were submitted to the GenBank database. The ITS sequence was compared with that of the most closely-related fungal species (identity values higher than 95%) in the NCBI database (<http://www.ncbi.nlm.nih.gov/>) using the BLAST program, in consultation with observed colony and spore morphology to confirm the taxonomic status of the investigated fungal isolate. The sequence of *Psilocybe cubensis* was used as an out-group. Bayesian trees constructed by PAUP 4.0b10 and MrBayes 3.2.6 after phylogenetic analysis of the ITS sequence data.

Screening of PKS and NRPS genes in tree peonies endophytic fungi

The highly conserved sequences of β-ketoacyl synthase (KS) domains are shared among all PKSs; thus, the KS domains are useful in screening for PKSs in fungi. Therefore, LC series primers (Table 1) were used to detect PKS genes in the fungal isolates.¹⁶ Similarly, the most conserved A domain can be used for PCR primer design to survey NRPSs gene diversity. Primers AUG003 and AUG007 (Table 1) were used for amplification of NRPS genes.¹⁷ The PCR reaction conditions were as follows: initial pre-heating at 94 °C for 5 min, 35 cycles of 95 °C for 1 min, 55 °C for 1.5 min, 72 °C for 3 min, and a final extension at 72 °C for 10 min. After amplification, the PCR products were inspected by electrophoresis on a 1.2% agarose gel stained with ethidium bromide (0.5 ng/mL agarose) by stirring gently for 15 min; the products were then visualized under UV light. Prior to cloning, PCR products were purified with DNA Gel Extraction Kit (San Prep SK8131, PR China). The sequences encoding the PKS or NRPS were cloned into a pUCM-T cloning vector (Sangon SK2211, PR China) and transformed into

competent *Escherichia coli* cell (B529303 Ultra-Competent Cell Preps Kit, PR China) according to the manufacturer's protocol. The purified plasmid (using SanPrep Column Plasmid Mini-Preps Kit B518191, PR China) was sequenced.

Date analysis

The colonization rate (CR) was calculated according to the method of Hata and Futai,¹⁸ CR = NCOL/Nt where NCOL is the number of segments colonized by each endophytic fungi; N_t is the total number of segments. The isolation rate (IR) was calculated as follow: IR = the number of EF isolated/the total number of fragments incubated.¹⁹ The Shannon diversity index (*H*) and the Simpson's diversity index (*D*) were used to analyze the diversity of endophytic fungi and calculated as follows: Shannon diversity index, Simpson's diversity index, where *k* is the total number of fungal taxon, and *P_i* is the relative abundance of taxon *i*. Evenness values were calculated following Pielou's Evenness Index. Pielou's Evenness Index *J* = *H*/log (*S*), where *H* is the Shannon–Weaver diversity index and *S* is the number of species (species richness).²⁰ Statistical analyses were performed using IBM SPSS Statistics Software (Version 20). The fungal phylotypes richness, the detection rates of PKSs and NRPS were subjected to ANOVA to test for significant differences between different types of tree peonies.

Results

Abundance and diversity of endophytic fungi

A total of 364 endophytic fungal isolates were isolated from asymptomatic leaf, stem, and root segments of tree peonies plants following a standard isolation protocol. Results showed that *P. suffruticosa* 'Luoyang Hong' exhibited the highest number of endophytic fungi (206 isolates), followed by *P. ostii* 'Luoyang Feng Dan' (98 isolates), *P. ostii* 'Feng Dan' (60 isolates) (*p* < 0.05) (Table 2). The colonization rate of *P. suffruticosa* 'Luoyang Hong' was the highest, followed by *P. ostii* 'Luoyang Feng Dan', while *P. ostii* 'Feng Dan' is the lowest. A similar situation exists with the IR. The isolation rate of *P. suffruticosa* 'Luoyang Hong' was significant higher than that of *P. ostii* 'Luoyang Feng Dan' and *P. ostii* 'Feng Dan'. The 364 isolated endophytic fungi were assigned to 156 morphospecies. All the morphotypes were identified based on the morphological characteristics and ITS sequence data (Table 3). Multiple alignment of the ITS sequence data was performed by Clustal W of MEGA ver. 6. MrModeltest 2.1 was used to choose the substitution model that best fit the data using the AIC criterion. The best model computed for Bayesian analysis was GTR + G. Bayesian analyses used one cold and three heated Monte Carlo Markov chains in two simultaneous runs. Bayesian analyses was computed with MrBayes 3.2.6 and carried out using 1.5×10^7 generations and a sample frequency of 100. The burn-in ratio was set at 0.25 (Fig. 1).

To characterize the biodiversity of our samples, we calculated Species richness (*S*), Shannon diversity index (*H*), Simpson's diversity index (*D*), and Pielou evenness index (*J*). The values obtained by these tests (17, 2.5757, 0.9006, and 0.9091, based on *P. ostii* 'Feng Dan'; 9, 1.7730, 0.7876, and 0.8069,

Shannon diversity index (H')	2.5757	1.7730	1.3458
Simpson's diversity index (D)	0.9006	0.7876	0.6125
Pielou's Evenness Index (J)	0.9091	0.8069	0.5845

based on *P. ostii* 'Luoyang Feng Dan'; 10, 1.3458, 0.6125, and 0.5845, based on *P. suffruticosa* 'Luoyang Hong', respectively) were shown in Table 2.

Community composition of endophytic fungi

In each of the three types of tree peonies, the composition of the endophytic fungi communities exhibited a high degree of variability. Among those detected, for *P. ostii* 'Feng Dan', a total of 17 different genera of endophytic fungi were isolated, *Phomopsis* was the dominant genus with relative frequency of 19.2%, followed by *Nigrospora*, *Alternaria* and *Pestalotiopsis* with relative frequencies of 15.4%, 7.7% and 7.7%, respectively; for *P. ostii* 'Luoyang Feng Dan', a total of 9 different genera of endophytic fungi were isolated, *Fusarium* was the dominant genus with relative frequency of 27.4%, followed by *Phoma*, *Alternaria* and *Paraconiothyrium* with relative frequencies of 23.5%, 19.6%, and 9.8%, respectively; for *P. suffruticosa* 'Luoyang Hong', a total of 10 different genera of endophytic fungi were isolated, *Alternaria* was the dominant genus with relative frequency of 55.7%, followed by *Fusarium* and *Pestalotiopsis* with relative frequencies of 25.7% and 5.8%, respectively (Fig. 2). A total of 26 different fungal genera were recovered from three types of tree peonies, of which, ten (38.5%) were exclusively isolated from *P. ostii* 'Feng Dan', four (15.4%) were only recovered from *P. ostii* 'Luoyang Feng Dan', four (15.4%) were merely obtained from *P. suffruticosa* 'Luoyang Hong', and eight (30.8%) were jointly found in the three types of tree peonies (Fig. 2). On the whole, the stems of tree peonies exhibited the highest number of endophytic fungi (221 isolates), followed by the leaves (85 isolates) and roots (58 isolates).

Identification of genes encoding bioactivity in tree peonies endophytic fungi

Degenerate PCRs were used to detect putative NRPS and PKS gene sequences originating from fungal endophytes in the DNA extracts. Amplification of fungal KS domains and A domains was confirmed via sequencing and BLASTX (translated) analysis. Based on the BLASTX analysis, a total of 69 endophytic fungi isolated from the three types of tree peonies were detected to contain fungal KS domain sequences (~700 bp). The amplified sequences possessed between 90% and 100% amino acid identity to known fungal PKSs. The detection rates of *P. ostii* 'Feng Dan' endophytic fungi, *P. ostii* 'Luoyang Feng Dan' endophytic fungi, *P. suffruticosa* 'Luoyang Hong' are 48.15%(13/27), 41.07%(23/56), and 44.59%(33/74) ($p < 0.05$), respectively (Table 4). A total of 8 endophytic fungi isolated from the three types of tree peonies were detected to contain fungal A domains sequences (~1500 bp). The amplified sequences possessed between 64% and 75% amino acid identity to known fungal NRPS. The detection rates of *P. ostii* 'Feng Dan' endophytic fungi, *P. ostii* 'Luoyang Feng Dan' endophytic fungi, *P. suffruticosa* 'Luoyang Hong' endophytic fungi are 11.11% (3/27), 7.14% (4/56), and 1.35% (1/74) ($p < 0.05$), respectively (Table 5).

Discussion

In this study, endophytic fungal isolated from three types of tree peonies were identified, and their communities' composition were analyzed. The research results indicate that the biodiversity of fungal endophytes in the three types of tree peonies exhibited a high degree of difference. *P. ostii* 'Feng

^a Fengdan, *Paeonia ostii* 'Feng Dan'; Luoyang Fengdan, *Paeonia ostii* 'Luoyang Feng Dan'; Luoyang Hong, *Paeonia suffruticosa* 'Luoyang Hong'.

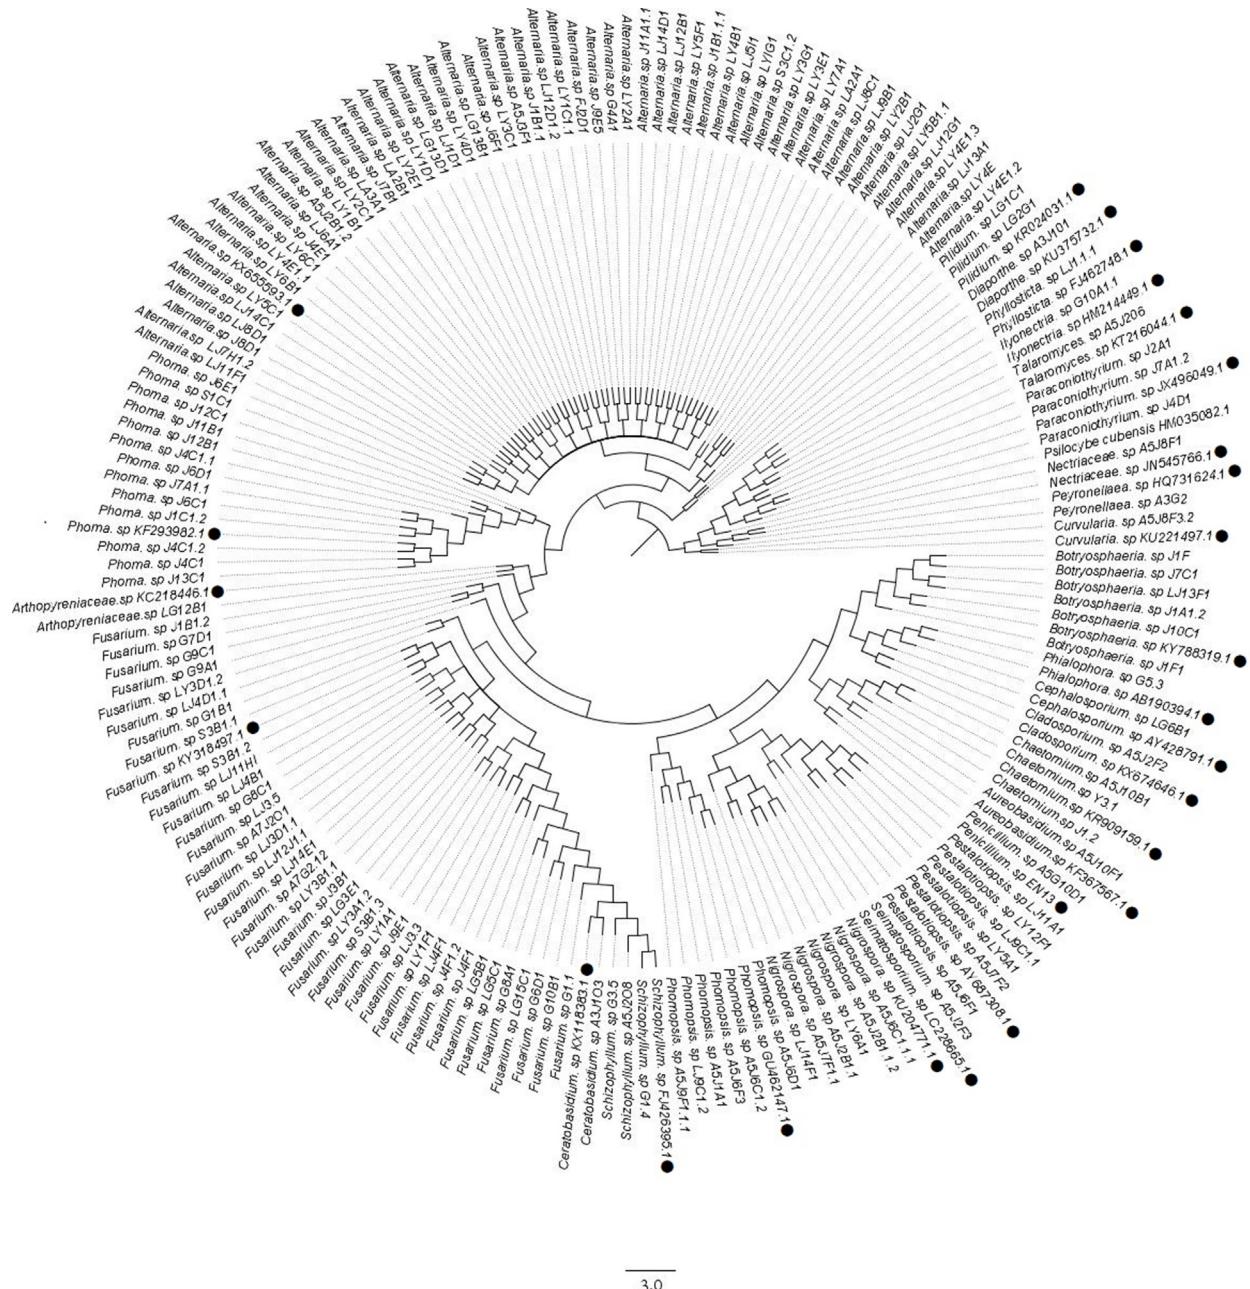

Fig. 1 – Phylogenetic tree based on the ITS1, 5.8S and ITS2 region of rDNA obtained from endophytic fungi of three types of tree peonies. The tree was constructed via the Bayesian inference method. An individual of each taxon isolated was used in the construction of the clustering together with a reference sequence retrieved from GenBank (●). The fungus *Psilocybe cubensis* was used as outgroup for the construction of the tree.

Dan' yielded low abundance strains and showed lower CR and IR, yet the Species richness (S), Shannon diversity index (H'), Simpson's diversity index (D) of *P. ostii* 'Feng Dan' were all higher than that of *P. ostii* 'Luoyang Feng Dan' and *P. suffruticosa* 'Luoyang Hong' (Table 2). There are altogether 26 different fungal genera recovered from three types of tree peonies, of which, 10 different fungal genera were exclusively isolated from *P. ostii* 'Feng Dan', 4 different fungal genera were only recovered from *P. ostii* 'Luoyang Feng Dan', 4 different fungal genera were merely obtained from *P. suffruticosa* 'Luoyang

Hong', and 8 different fungal genera were jointly found in the three types of tree peonies. Compared with *P. ostii* 'Luoyang Feng Dan' and *P. suffruticosa* 'Luoyang Hong', *P. ostii* 'Feng Dan' which is the raw material of Daodi Cortex Moutan has more types of endophytic fungi. The diversity of *P. ostii* 'Feng Dan' endophytic fungi is the highest, followed by that of *P. ostii* 'Luoyang Feng Dan', the diversity of endophytic fungi from the *P. suffruticosa* 'Luoyang Hong' is the lowest. In this study, *P. ostii* 'Feng Dan' and *P. ostii* 'Luoyang Feng Dan' are essentially the same variety of tree peonies, they just grow

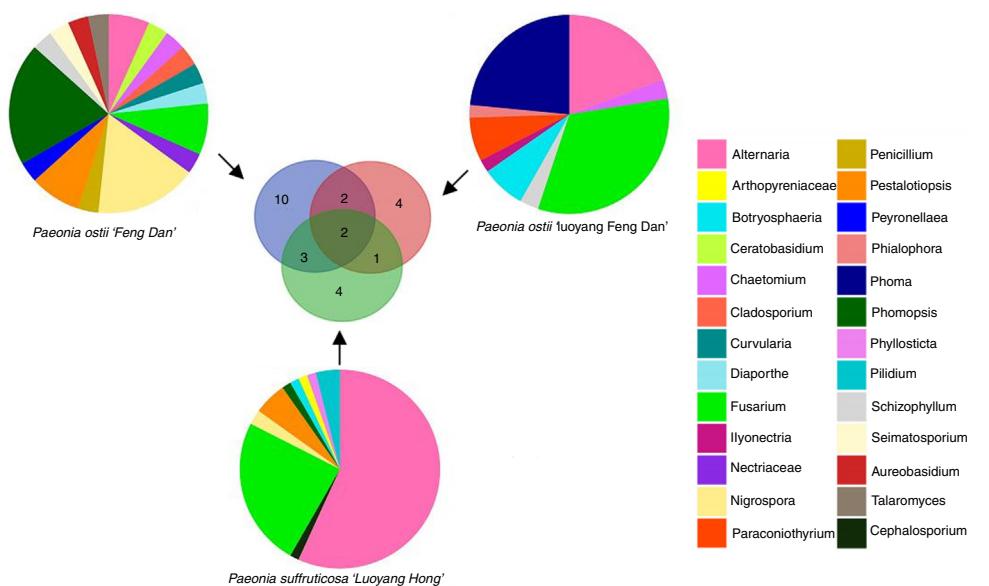

Fig. 2 – Pie charts show the relative abundance of the dominant culturable endophytic fungi phyla in three types of tree peonies. Venn's diagrams showing unique and shared genus in culturable endophytic fungi of *P. ostii* 'Feng Dan', *P. ostii* 'Luoyang Feng Dan' and *P. suffruticosa* 'Luoyang Hong' samples.

^a Fengdan, *Paeonia ostii* 'Feng Dan'; Luoyang Fengdan, *Paeonia ostii* 'Luoyang Feng Dan'; Luoyang Hong, *Paeonia suffruticosa* 'Luoyang Hong'.

in the different geographical environment. But the diversity of *P. ostii* 'Feng Dan' endophytic fungi is significantly higher than that of *P. ostii* 'Luoyang Feng Dan' endophytic fungi. *P. ostii* 'Luoyang Feng Dan' and *P. suffruticosa* 'Luoyang Hong' are the different varieties of tree peonies, they grow in the same geographical environment. There is not much difference between the endophytic fungi diversity of *P. ostii* 'Luoyang Feng Dan' and *P. suffruticosa* 'Luoyang Hong'. The results of the above studies suggest that, compared with the variety of tree peonies, geographical environment plays a more important role in affecting the diversity of tree peonies endophytic fungi.

From the perspective of endophytic fungi community composition, all the three types of tree peonies have different dominant genera. Ecological or environmental conditions,

such as temperature, humidity, illumination, geographic location, and vegetation significantly affected the distribution pattern and population structure of the endophytic fungi.²¹ *Phomopsis* is the dominant genus in the endophytic fungi community of *P. ostii* 'Feng Dan'. That may have relevance to soil nutrition and geochemistry characteristic of Tongling city, Anhui Province, China. The study on the soil Cu, Cd, Pb and Zn at the copper-tailings reservoir of Tongling City showed that the Cu and Cd contents in soil were 4.36–14.43 and 3.67–3.86 times of the 2nd China national standard for soil environmental quality, respectively.^{22,23} *Phomopsis* sp. is an ascomycete, that has attracted researcher's attention as a potential tool for heavy metal (copper, lead, zinc, etc.) contamination remediation. Research results indicate that after 24 h contact time,

up to 870 mmol/g of lead, 390 mmol/g of copper, 230 mmol/g of cadmium, 150 mmol/g of zinc and 110 mmol/g of nickel ions are adsorbed into *Phomopsis* sp. biomaterial.^{24,25} In addition, endophytic fungi of *Phomopsis* sp. are excellent potential sources of novel, bioactive natural products for exploitation in medicine, agriculture, and industry.^{26,27} *Fusarium* and *Alternaria* are the dominant genera in the endophytic fungi community of *P. ostii* ‘Luoyang Feng Dan’ and *P. suffruticosa* ‘Luoyang Hong’. They are the major plant pathogenic genera and the common genera in plant endophytic fungi community.^{28–31}

Over centuries of treating disease and attempting to preserve health, ancestors of the Chinese people developed the traditional Chinese medicine (TCM). In addition, China also has abundant natural resources of medicinal materials, which are the material basis for the application of TCM theory in preventing and treating disease. As the essence of Chinese medicinal materials, Daodi medicinal material has been playing an important role in treating disease and preserving health for thousands of years.¹ Cortex Moutan, which was produced from *P. ostii* ‘Feng Dan’ in Tongling city, located in Anhui Province, is considered as Daodi medicinal material. However, Cortex Moutan, which was produced from *P. ostii* ‘Feng Dan’ that were transplanted in other regions of China or from other peony varieties, is called non-Daodi medicinal material. To date, the dominant factor of Daodi Cortex Moutan forming is not yet clear. Bioactive components are the material basis for Daodi medicinal material to exert positive effect in preventing and treating disease. The most intrinsic difference between Daodi medicinal material and non-Daodi medicinal material is the difference in the types and amounts of bioactive components in medicinal plant. The NRPS and PKS are responsible for synthesizing many secondary metabolites that exhibit an important biological activity and may be valuable drugs.³² NRPS and PKS genomic analysis of the endophytic fungus reveals its potential for synthesis of natural products.^{32,33} In this study, NRPS and PKS gene sequences originating from fungal endophytes of three types of tree peonies were detected by Degenerate PCRs. As can be seen from the results (Tables 4 and 5), the PKSs and NRPS detection rates of endophytic fungi from *P. ostii* ‘Feng Dan’, which is the raw material of Daodi Cortex Moutan, are both the highest among the three types of tree peonies. The results of the above studies indicate that the endophytic fungi from *P. ostii* ‘Feng Dan’ have bigger potential for synthesis of natural products.
