

A new species of *Trichomycterus* (Siluriformes: Trichomycteridae) from lagoa Feia drainage, southeastern Brazil

Sergio M. Q. Lima¹, Henrique Lazzarotto² and Wilson J. E. M. Costa³

Trichomycterus caipora, new species, is described from rio Macabu basin, lagoa Feia drainage, serra de Macaé, southeastern Brazil. The new species is distinguished from its congeners from southern and southeastern Brazil by the combination of: the presence of nine pectoral-fin rays, caudal fin emarginated and high number of opercular and interopercular odontodes. Ecological notes are presented and putative phylogenetic relationships and characters shared with congeners are discussed.

Trichomycterus caipora, espécie nova, é descrita para a bacia do rio Macabu, drenagem da lagoa Feia, serra de Macaé, sudeste do Brasil. A nova espécie distingue-se dos demais *Trichomycterus* do sul e sudeste do Brasil pela combinação: da presença de nove raios na nadadeira peitoral, nadadeira caudal emarginada e elevado número de odontódeos operculares e interoperculares. Dados ecológicos são apresentados e as supostas relações filogenéticas e caracteres compartilhados com espécies do gênero são discutidos.

Key words: Catfishes, *Trichomycterus caipora*, Freshwater fishes, Atlantic Forest, Rio de Janeiro State, rio Macabu basin.

Introduction

The family Trichomycteridae is a monophyletic assemblage of small freshwater catfishes with 41 genera and approximately 200 species, distributed from Patagonia to Costa Rica, in both sides of Andes (de Pinna & Wosiacki, 2003; de Pinna, 1998). Trichomycterid genera are usually constituted of few species, and are all defined by synapomorphies (de Pinna & Wosiacki, 2003), except for *Trichomycterus* Valenciennes, which is apparently non-monophyletic (de Pinna, 1989, 1992). With more than a hundred nominal species, the genus comprises most of the trichomycterids. It is also the only genus represented in both sides of Andes, including the Andean altiplano (de Pinna & Wosiacki, 2003).

Despite the large number of species and taxonomic problems, many species of *Trichomycterus* have been described recently (e.g., Fernández & Schaefer, 2005; Sarmento-Soares

et al., 2005; Wosiacki, 2005; Wosiacki & Oyakawa, 2005; Alencar & Costa, 2006; Fernández & Osinaga, 2006; Castellanos-Morales, 2007; Fernández & Chuquihuamaní, 2007; Fernández & Miranda, 2007; Castellanos-Morales, 2008; Wosiacki & de Pinna, 2008a,b) and many more are waiting to be described, since the majority of species have limited distribution, displaying a high level of endemism (Eigenmann, 1918; Costa, 1992; Bockmann & Sazima, 2004). Since just a few species are known to occur outside the watersheds from which they were described [e. g., *Trichomycterus brasiliensis* Lütken and *T. zonatus* (Eigenmann)] and these wide-range species may constitute species-complexes (Barbosa & Costa, 2003; Bockmann & Sazima, 2004), the typical approach for osteological and morphological comparison is to focus only on the 49 southern and southeastern Brazilian species of *Trichomycterus* [*Talbinotatus* Costa, *T. alternatus* (Eigenmann), *T. auroguttatus* Costa, *T. brasiliensis* Lütken, *T. candidus*

A new species of *Trichomycterus* from rio Macabu basin, an isolated river basin draining into a lake (lagoa Feia), in northern Rio de Janeiro State, southeastern Brazil, is herein described.

Material and Methods

Measurements and counts follow Costa (1992). Measurements are presented as percentages of standard length (SL), except for subunits of head, which are presented as percentage of head length. Counts of procurrent caudal-fin rays, vertebrae, branchiostegal rays, teeth and odontodes were made only in cleared and stained specimens (c&s) prepared according to Taylor & Van Dyke (1985). Additional comparative material is listed below. Morphological data of *T. castroi*, *T. concolor*, *T. crassicaudatus*, *T. cubataonis*, *T. davi*s, *T. diabolus*, *T. guaraquessaba*, *T. igobi*, *T. iheringi*, *T. itacambirussu*, *T. itacarambiensis*, *T. jacupiranga*, *T. jequitinhonhae*, *T. landinga*, *T. maracaya*, *T. mboyicy*, *T. naipi*, *T. nigricans*, *T. paolence*, *T. papilliferus*, *T. paquequerensis*, *T. plumbeus*, *T. stawiarski*, *T. taroba*, *T. trefauti*, *T. triguttatus*, *T. tupinamba*, and *T. vermiculatus* were found in the original descriptions of each species. Tissue samples from two paratypes were deposited in Laboratório de Biodiversidade Molecular (LBDM). Abbreviations for institutions are: MCP, Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul, Porto Alegre; MNRJ, Museu

Nacional, Rio de Janeiro; MZUSP, Museu de Zoologia da Universidade de São Paulo, São Paulo; and UFRJ, Universidade Federal do Rio de Janeiro, Rio de Janeiro.

Trichomycterus caipora, new species

Figs. 1-2

Holotype. UFRJ 6583, 114.6 mm SL; Brazil, Estado do Rio de Janeiro: Município de Conceição de Macabu, lagoa Feia drainage, rio Macabu basin, rio Macabu upstream the confluence of rio Carocango and rio Macabu, 22°04'51.8"S 41°58'55.3"W, 28 June 2006, S. Lima, H. Jabor & H. Lazzarotto.

Paratypes. UFRJ 7247, 12, 69.6-116.2 mm SL; UFRJ 7614, 3 (c&s), 69.1-75.0 mm SL; MNRJ 31924, 77.9-87.6 mm SL; all collected with holotype. UFRJ 7257, 69.0-69.9mm SL; Brazil, Estado do Rio de Janeiro, Município de Conceição de Macabu, rio Macabu basin, rio Carocango, upstream Cachoeira da Amorosa, tributary to rio Macabu, same collectors and date as holotype.

Diagnosis. Similar to *T. giganteus*, *T. immaculatus* and *T. nigricans* and distinguished from the remaining congeners from southern and southeastern Brazil by having nine pectoral-fin rays (vs. eight or fewer) and more odontodes (interopercular 59-70, vs. 19-52, opercular 23-30, vs. 10-20). Easily distinguished from *T. giganteus*, *T. immaculatus*, and *T. nigricans* by having the caudal fin emarginate (vs. truncate). It further differs from *T. giganteus* by having shorter nasal and maxillary barbels (nasal reaching posterior margin of eye vs. reaching pectoral-fin base; maxillary reaching anterior portion of interopercular patch of odontodes vs. reaching anterior third of pectoral fin), and from *T. immaculatus* and *T. nigricans* by the presence of four irregular longitudinal rows of rounded blotches on trunk (vs. homogeneous colour pattern).

Description. Morphometric data for holotype and paratypes given in Table 1. Body moderately deep, subcylindrical on anterior portion, compressed on caudal peduncle. Dorsal profile slightly convex between snout and end of dorsal-fin base, approximately straight from this point to base of caudal fin. Ventral profile convex between lower jaw and end of anal-fin base, straight on caudal peduncle.

Head depressed, longer than wider, subtriangular in dorsal view. Eye at middle of head, orbital rim not free. Skin covering eye thin and translucent. Snout blunt. Mouth subventral. Lower lip with conspicuous lateral fleshy lobes. Maxilla slightly longer than premaxilla. Teeth conical. Tip of nasal barbel reaching posterior margin of eye. Tip of maxillary and rictal barbels reaching anterior portion of interopercular patch of odontodes. Base of maxillary and rictal barbels, lips and ventral portion of head covered by papillae. Branchial membranes thick, united to isthmus anteriorly by thin flap of skin. Seven branchiostegal rays. Interopercular odontodes 65-70; opercular patch of odontodes wide, with 26-28 odontodes;

Fig. 1. *Trichomycterus caipora*, lateral, dorsal and ventral views. Holotype, UFRJ 6583; 114.6 mm SL. Brazil, Rio de Janeiro, Conceição de Macabu, rio Macabu upstream the confluence of rio Carocango and rio Macabu.

odontodes conical, opercular odontodes wider than interopercular odontodes; opercular odontodes arranged vertically. Medial margin of autopalatine slightly concave; posterior process of autopalatine slightly shorter than autopalatine without posterior process. Lacrimal about one fourth supraorbital length; supraorbital rod-like. Metapterygoid small, without distinct processes. Anterodorsal surface of hyomandibula with weak concavity (Fig. 3). Third supraorbital pore fused (9 in 16 specimens), sometimes paired with each pore closer to symmetrical pore than to orbit. Anterior section of infraorbital canal present.

Pectoral-fin rays i,8. Pectoral fin somewhat triangular, lateral and posterior edges slightly convex. First pectoral-fin ray terminating as long filament, about 20-40% of pectoral-fin length. Pelvic fin about 2/3 of anal fin length, tip not reaching anal fin or covering urogenital pore, tip at vertical through

base of first branched dorsal-fin ray; pelvic-fin bases separated by interspace. Dorsal and anal fins approximately triangular. Dorsal-fin origin at vertical between centrum of 17th and 18th vertebra. Anal-fin origin posterior to vertical through dorsal-fin base, and through centrum of 23rd or 24th vertebra. Caudal fin emarginate. Dorsal-fin rays vii,5-6; anal-fin rays v,5; pelvic-fin rays i,4; principal caudal-fin rays 6+7, dorsal procurrent rays 12-16, ventral procurrent rays 11-15. Free vertebrae 35-36; precaudal vertebrae 12; caudal vertebrae 23-24; pleural ribs 12. Upper hypural plates separated, dorsal plate as wide as ventral plate.

Coloration. Side of body orangish yellow, dorsal half yellowish brown, forming rounded blotches on trunk arranged in four irregular longitudinal rows: one along dorsal region, one along dorsolateral region (both in vertical from opercular patch

Fig. 2. *Trichomycterus caipora* immediately after preservation, showing phenotypic color variation, paratypes, UFRJ 7247; **a**, 116.2 mm SL; **b**, 100.4 mm SL. Brazil: Estado do Rio de Janeiro: Conceição de Macabu.

of odontodes to caudal peduncle), one along midlateral region (from opercular patch of odontodes to caudal peduncle), all rows with chromatophores present both in superficial and deep layer of integument, and one along ventrolateral region (from behind pectoral fin to posterior margin of anal-fin base), with chromatophores restricted to inner layer of integument, and faint brown dots below lateral midline, venter yellowish white. Some specimens show dorsal and dorsolateral rows coalescent, forming single dark band on dorsal portion of body and head. Midlateral blotches sometimes coalesce forming well-defined or interrupted stripe (Fig. 2). Head orangish yellow, with chromatophores concentrated in the supraorbital and preopercular regions. Opercular and interopercular patches of odontodes light yellow; nasal barbel dark grey,

maxillary and rictal barbels light grey. Iris yellow. Dorsal fin pale yellow with orangish brown spots on basal half, hyaline with brown dots on distal half. Caudal fin pale orangish brown with small dark brown spots, distal fourth hyaline. Pectoral and anal fins yellow with brown spots on proximal region. Pectoral-fin filament white. Pelvic fin pale yellow. Fins yellowish hyaline. Juvenile specimens with lighter homogeneous grayish pattern.

Etymology. From the Tupi, *kaa'pora* (forest dweller), a forest dwelling creature of the Tupi mythology, with orange hair and a protector of the wildlife; an allusion to the fact that the new species is endemic to the Atlantic Rain Forest and possesses orangish yellow head. A noun in apposition.

Table 1. Morphometric data of holotype and eleven paratypes of *Trichomycterus caipora*, from rio Macabu basin, Rio de Janeiro State, southeastern Brazil.

	Holotype	Min	Max	Mean	SD
Standard length (mm)	114.6	70.3	116.2		
Head length (mm)	22.0	13.2	22.7		
	Percents of standard length

Eye diameter	13.2	11.0	13.6	12.7	0.8

Distribution. *Trichomycterus caipora* is only known from the type locality in the mountain streams of the rio Macabu basin, lagoa Feia drainage, serra de Macaé, northern Rio de Janeiro State, southeastern Brazil (Fig. 4). The new species can be found in several sites in the upper and middle reaches of the rio Macabu and its tributary streams.

Ecological notes. Rio Macabu basin encompasses an area of approximately 1,076 km². Rio Macabu flows for about 120 km until it reaches lagoa Feia, an isolated lagoon in northern Rio de Janeiro State (Bizerril & Primo, 2001). Its headwaters are located in serra de Macaé mountain range, at about 1,500 m above sea level, in areas partially covered with secondary Atlantic forest. The impact of human activities is visible along the entire course of rio Macabu. On the mountain slopes the main visible impacts are the presence of several buildings on the river banks, and also the deforestation for several purposes, such as agriculture and cattle raising.

Trichomycterus caipora was collected in clear, fast flowing streams and small rivers, with substrate composed mainly by rocks, gravel and coarse sand, in altitudes between 80 and 210 m. Since no sampling was performed above this altitude, it is possible that *T. caipora* possesses a more extent longitudinal distribution. The original Atlantic forest vegetation is rare along the river banks; marginal vegetation, when present, was composed mainly by grass from adjacent pastures. Specimens were collected on the main channel of streams, in sites ranging from about 6 m to 15 m stream width, in depths of about 50 cm, on substrate composed by varied size rocks, in spots with medium to fast water current.

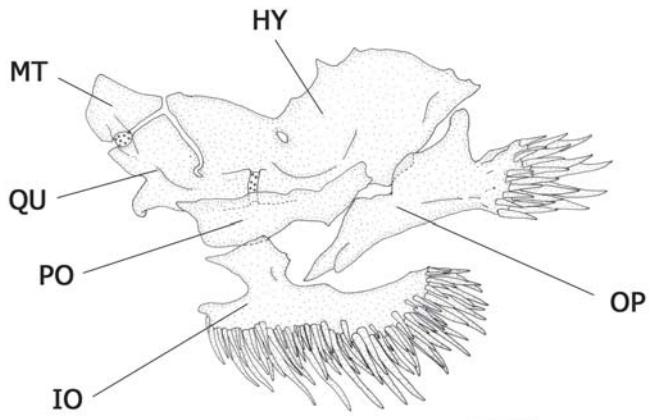

Fig. 3. Left suspensorium and opercular series of *Trichomycterus caipora*, UFRJ 7614, 69. 1 mm SL. Lateral view. Abbreviations : HY, hyomandibula ; IO, interoperculo ; MT, metapterygoid ; OP, opercle ; PO, preopercle ; QU, quadrate. Scale bar = 1 mm.

Trichomycterus caipora seems to be nocturnal species. Only five juvenile specimens were captured in daylight, whereas 16 specimens were easily collected at dawn and night time. Underwater observations during daytime did not detect active individuals of *Trichomycterus caipora*. Only one individual was seen hiding under plant debris and rocks, in a shallow area of a pool just downstream from Cachoeira Amorosa, a 15 m high waterfall. Furthermore, three specimens of *T. aff. zonatus* were caught at this period always in sand beds, while 17 specimens were captured during daylight, when they were swimming active or buried in sand. This could suggest diel and microhabitat segregation between these congeneric species.

Other species collected with *Trichomycterus caipora* were *Neoplecostomus microps* (Steindachner), *Ancistrus multispinus* (Regan), and *Characidium* sp. Furthermore, individuals of *Geophagus brasiliensis* (Quoy & Gaimard) and *Astyanax* sp. were also observed.

Discussion

Although the relationships among large clades within the family Trichomycteridae are relatively well understood (de Pinna, 1998), the relationships among the Trichomycterinae, at the species-level are scarce and not based on strictly phylogenetic criteria (Costa, 1992; de Pinna, 1992; Barbosa & Costa, 2003; Bockmann & Sazima, 2004; Bockmann *et al.*, 2004; Wosiacki & de Pinna, 2008a,b). Besides the enormous specific diversity of *Trichomycterus*, the non-monophyletic nature of the Trichomycterinae (de Pinna, 1989) makes it difficult to establish well defined outgroups and, consequently, consistent polarities and unequivocal intrageneric synapomorphies (de Pinna, 1992; Bockmann & Sazima, 2004). However some features shared

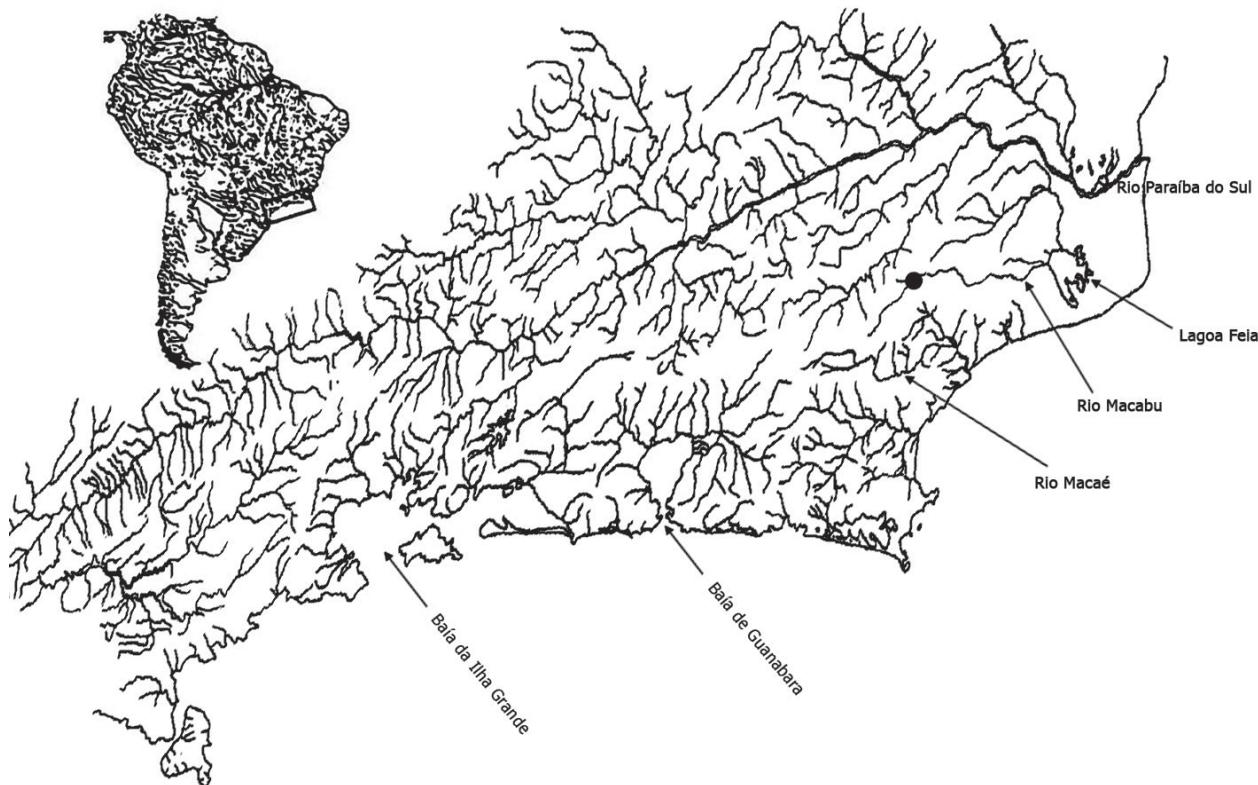

Fig. 4. Map of southeastern Brazil showing geographic distribution of *Trichomycterus caipora*. Symbol represents more than one sampling locality.

by *Trichomycterus caipora* and other *Trichomycterus* species, as well as their putative relationships can be discussed. *Trichomycterus caipora* could be closely related to the type species of the genus, *T. nigricans*, and to *T. immaculatus* and *T. giganteus* based on the presence of nine pectoral-fin rays (i+8) and more odontodes (interopercular 59-70, vs. 19-52, opercular 23-30, vs. 10-20). Numerous opercular odontodes can be considered as a derived condition among the Trichomycterinae because opercular odontodes are absent in *Copionodon* de Pinna, and occurs in small number in *Trichogenes longipinnis* Britski & Ortega (6-12), the phylogenetically basal trichomycterids (de Pinna, 1998), and in small number in most species of *Trichomycterus* and in other trichomycterids. Within the Trichomycterinae, *Hatcheria macraei* (Girard) has 11-12, *Bullockia maldonadoi* (Eigenmann) 13-14 and the other *Trichomycterus* species usually have 8-20 opercular odontodes.

Trichomycterus caipora also shares with *T. giganteus* a broad stripe along the trunk, a feature that is absent in *T. nigricans* and *T. immaculatus*. *Trichomycterus caipora* usually presents the third supraorbital pore fused, as in *T. giganteus* and *T. nigricans* (Arratia, 1998), and distinct from *T. immaculatus*, which has the third supraorbital paired. A fused third supraorbital is also present in *T. jacupiranga*, which is distinguished from *T. caipora* by having only eight

pectoral-fin rays (Wosiacki & Oyakawa, 2005).

The color pattern in *Trichomycterus caipora*, composed by blotches on trunk arranged in four longitudinal rows is present in many other Trichomycterinae species (Bockmann & Sazima, 2004). In *T. caipora* the blotches sometimes coalesce forming well-defined [e.g., *T. giganteus*, *T. maracaya*, *T. pauciradiatus*, and *T. variegatus*] or interrupted stripe [e.g., *T. albinotatus*, *T. alternatus*, *T. caudofasciatus*, *T. maracaya*, and *T. variegatus*].

Among the described species of *Trichomycterus* from southern and southeastern Brazil, an emarginated caudal fin occurs only in *T. florensis*, *T. paquequerensis* (Miranda-Ribeiro, 1943) and in juveniles of *T. crassicaudatus* (Wosiacki & de Pinna, 2008b). However, *T. caipora* can be distinguished from *T. florensis* and *T. paquequerensis* by having a color pattern composed of four irregular longitudinal rows of rounded blotches on trunk (vs. transversal dark bars and homogeneous colour pattern, respectively). *Trichomycterus caipora* and all other species of *Trichomycterus* could be easily distinguished from *T. crassicaudatus* by the latter species having a forked caudal fin in adults and the deepest caudal peduncle within the Trichomycteridae (Wosiacki & de Pinna, 2008b).

Although not diagnosed by any autapomorphy, the combination of characters mentioned herein could easily diag-

nose the new species. The possible close relationship with the type species of the genus, *T. nigricans*, could indicate that *T. caipora* would continue to be a *Trichomycterus* species, even if the genus becomes divided into many genera (de Pinna & Wosiacki, 2003)

Comparative material examined. Copionodontinae: *Copionodon* sp., MZUSP 48962, 8 (2 c&s). Trichogeninae: *Trichogenes longipinnis*, UFRJ 0861, 3, UFRJ 0682, 2 (c&s).
