ABSTRACT. Salticidae is the most diverse family of Araneae and in Brazil, there are 667 species. Among these species, five are synanthropic exotics: *Plexippus paykulli* (Audouin, 1826), *Hasarius adansoni* (Audouin, 1826), *Menemerus bivittatus* (Dufour, 1831), *M. niglig* Wesolowska & Freudenschuss, 2012 and *Thyene coccineovittata* (Simon, 1886). To understand the current distribution of these species in Brazil, seven collections of 643 lots were examined from seven Brazilian zoological collections. The synanthropic exotic species with the highest records were *Plexippus paykulli*, *Menemerus bivittatus*, and *Hasarius adansoni*, generally collected and associated with human dwellings and buildings. They are present in all regions (North, Northeast, Midwest, and South macro-regions), with the largest region, in all regions of the country in 22 states and 98 municipalities, followed by *Hasarius adansoni* in 17 states and 88 municipalities, *Menemerus bivittatus* in 19 states and 68 municipalities. *Menemerus niglig* and *Thyene coccineovittata* are from recent introductions that occurred in the city of Rio de Janeiro, Rio de Janeiro, Brazil.

KEYWORDS. Spiders, distribution geographics, alien species.

RESUMO. As aranhas Salticidae exóticas sinantrópicas no Brasil (Araneae). Salticidae é a família mais diversa de Araneae e no Brasil ocorrem 667 espécies, dentre elas cinco são exóticas sinantrópicas: *Plexippus paykulli* (Audouin, 1826), *Menemerus bivittatus* (Dufour, 1831), *Hasarius adansoni* (Audouin, 1826), *Menemerus niglig* Wesolowska & Freudenschuss, 2012 e *Thyene coccineovittata* (Simon, 1886). Foram examinados 643 lotes destas cinco espécies no Brasil, depositados em sete coleções zoológicas brasileiras. As espécies exóticas sinantrópicas com maior número de registros foram *Plexippus paykulli*, *Hasarius adansoni* e *Menemerus bivittatus*, na maioria dos casos coletadas associadas a habitações e edificações humanas. Elas estão presentes em todas as macrorregiões do país (Norte, Nordeste, Centro-Oeste, Sudeste e Sul), sendo *P. paykulli* a que possui a maior distribuição, ocorrendo em 22 estados e 98 municípios, seguido de *H. adansoni* em 17 estados e 88 municípios e *M. bivittatus* em 19 estados e 68 municípios. *Menemerus niglig* e *Thyene coccineovittata*, são introduções recentes, ocorrendo apenas na cidade do Rio de Janeiro, Rio de Janeiro, Brasil.

PALAVRAS-CHAVE. Aranhas, distribuição geográfica, espécies exóticas.

Urban environments went through anthropological processes with a high demand for natural resources and inadequate discard of tailings (HOGAN *et al.*, 2001), creating urban niches with conditions for some arachnids to establish their populations (ROBINSON, 2005). Among these are the spiders (Araneae), with their ability to occupy different niches (PICKETT *et al.*, 2001; SWANSON *et al.*, 2009), occupying mainly the peridomicile of the residences (e.g. walls, gardens, other constructions) (ROBINSON, 2005).

In Brazil, there is still no national survey of Brazilian synanthropic spiders, but INDICATTI & BRESCOVIT (2008) reported 92 species of urban spiders in the city of São Paulo. Some other authors contributed with surveys of populations of synanthropic species in the states of Pará and Maranhão (RODRIGUES *et al.*, 2017), Bahia (BRAZIL *et al.*, 2005), and in several other northeastern states (CARVALHO *et al.*, 2014).

One of the easily found families is the Salticidae (jumping spiders) (MONDAL *et al.*, 2020), spiders of these

are small, not exceeding 10 mm in size, with eight eyes, arranged in ocular formula 4–2–2, being the two medium eyes anterior, larger than the others (MONDAL *et al.*, 2020; PLATNICK, 2020). It is the most diverse family within Araneae, having more than 6,395 species distributed worldwide (WORLD SPIDER CATALOG, 2022). Of these, 670 species occur in Brazil, being the largest diversity hotspot in the world, and followed by China with 574 species and Australia, with 507 species (METZNER, 2020).

Some occupations of urban niches occur through the accidental or intentional introduction of alien species (ROBINSON, 2005), under favorable conditions, these invasions can affect arthropod assemblages since spiders are efficient predators (NYFFELER, 2000; NENTWIG, 2015).

In Brazil, at least 36 introductions of spiders were recorded (INDICATTI & BRESCOVIT, 2008; BRESCOVIT *et al.*, 2019; MARIANTE & HILL, 2019; 2020), of these, five species belong to Salticidae: *Plexippus paykulli* (Audouin, 1826),

Menemerus bivittatus (Dufour, 1831), *M. niglig* Wesołowska & Freudenschuss, 2012 *Hasarius adansonii* (Audouin, 1826), and *Thyene coccineovittata* (Simon, 1886).

This work aims to document the distribution of Salticidae species introduced in Brazil, presenting morphological and diagnostic data of the species, mapping the distribution of the species, and illustrating the species, with emphasis on the genital structure.

MATERIAL AND METHODS

The specimens used in this work are deposited at the following institutions (abbreviations and curators in parentheses): Instituto Butantan, São Paulo, Brazil (IBSP, A. D. Brescovit); Museu de Ciências Naturais, SEMA, Porto Alegre, Brazil (MCN, R. Ott); Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil (MNRJ, A. B. Kury); Museu Paraense Emílio Goeldi, Belém, Brazil (MPEG, A. B. Bonaldo); Museu de Zoologia, Universidade de São Paulo, São Paulo, Brazil (MZSP, R. Pinto da Rocha); Centro de Coleções Taxonômicas, Universidade Federal de Minas Gerais, Belo Horizonte, Brasil (UFMG, A. J. Santos); Laboratório de Diversidade de Aracnídeos, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil (UFRJ, R. Baptista).

To assist in the determination of synanthropic species, we used the online database provided by METZNER (2020). The photos of the body in dorsal view, the male palp and the female genitalia, and maps were taken following the methodology used by BRESCOVIT *et al.* (2019).

TAXONOMY

Plexippus paykulli (Audouin, 1826)

(Figs 1–6; 31)

Attus paykullii AUDOUIN, 1826:409, plate 7, fig. 22 (Male holotype from Egypt); SIMON, 1868:601 (descr. female).

Hasarius paykulli: SIMON, 1876:81.

Menemerus paykulli: THORELL, 1881:501.

Plexippus paykulli: PECKHAM & PECKHAM, 1886:296; SIMON, 1903:712, 735, figs 839–841.

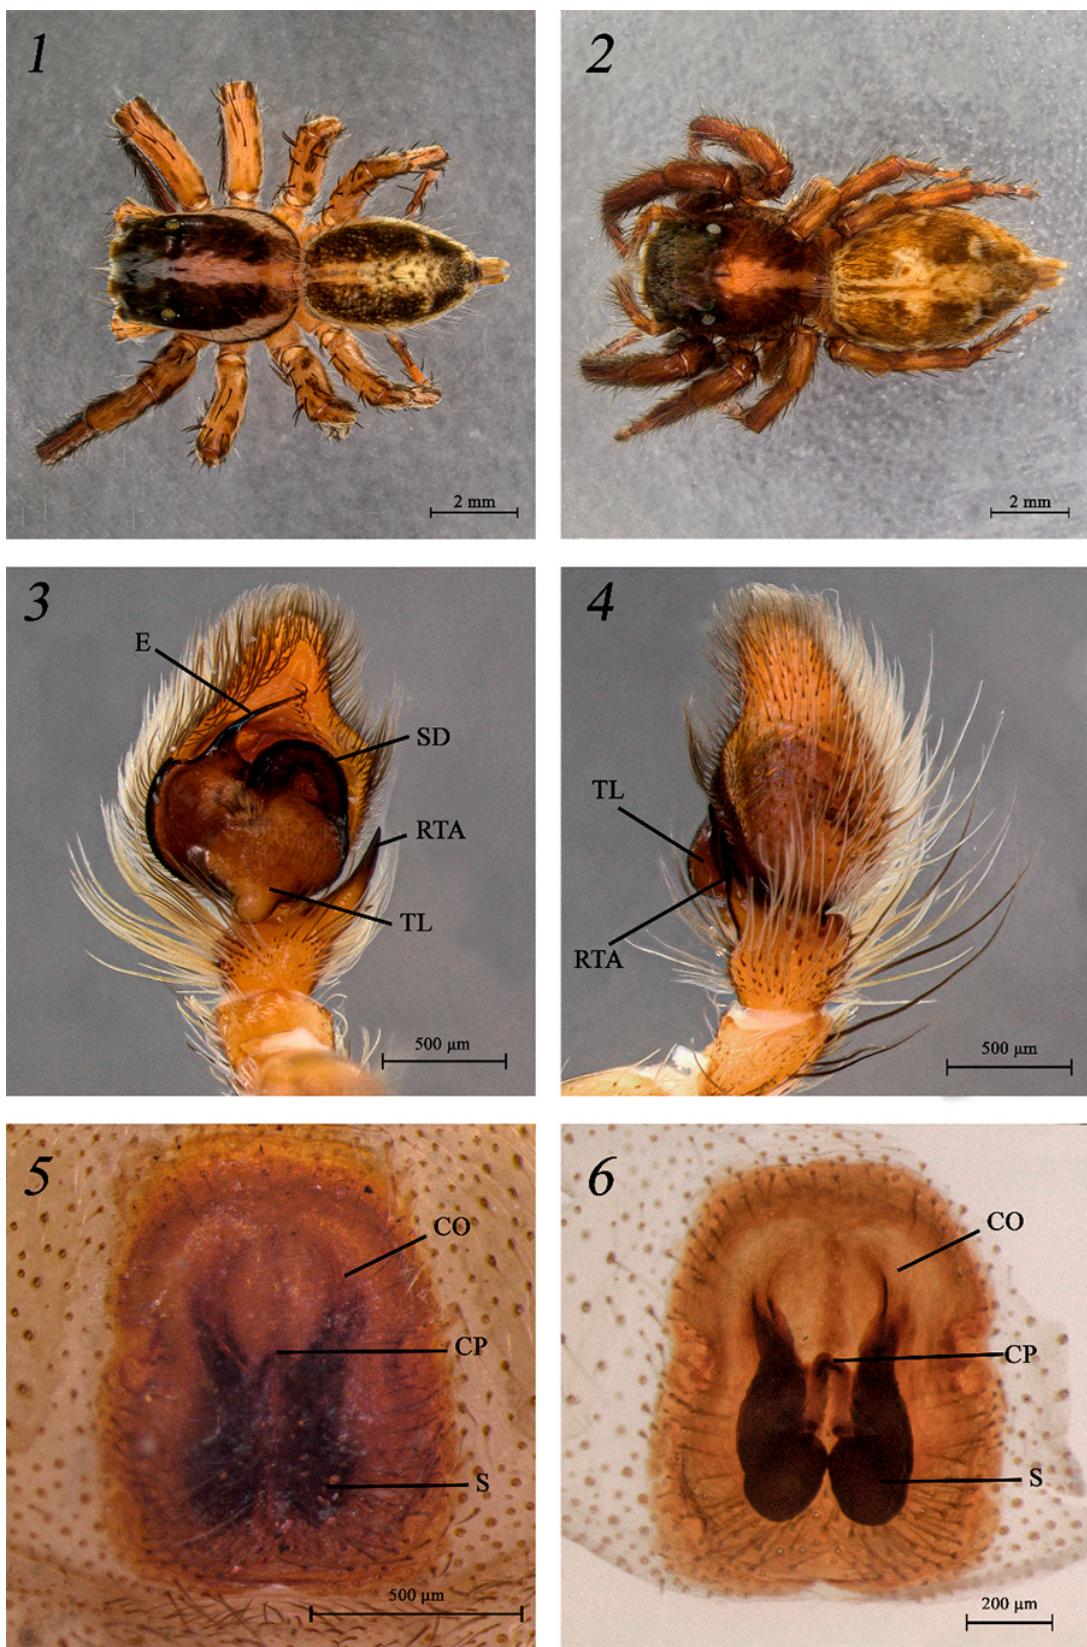

Thotmes paykulli: F. O. PICKARD-CAMBRIDGE, 1901:240, plate 20, fig. 21. (Check other synonyms in the WORLD SPIDER CATALOG, 2022).

Diagnosis. *Plexippus paykulli* differ from other synanthropic Salticidae for being more robust and for their carapace decorated with three light bands, one in the center of the back and two on the sides (Figs 1, 2), male palp with a long and robust retrolateral tibial apophysis, rounded tegulum, and thinned embolus, arranged above the spermatic duct (Figs 3, 4). The female differs from the other synanthropic species by the epigynum with an oval plate, with lateral edges approaching each other at the base and farther apart at the distal end (Figs 5, 6).

Records in the World. *Plexippus paykulli* is a species of African origin and was introduced in Europe, the Middle East, India, China, Japan, Korea, Thailand, the Philippines, Papua New Guinea, Australia, the Pacific Islands, and the Americas (WORLD SPIDER CATALOG, 2022).

Natural history. Records in Brazilian zoological collections (Fig. 31) indicate that in Brazil the species occurs almost exclusively in urban environments, with 74 records in houses and 20 records in other buildings (e.g. sheds, churches, and other commercial constructions) (Tab. I). In the literature, it is found in the soil, bushes, buildings, doors, windows, concrete, or stone walls (JACKSON & MACNAB, 1989; MONDAL *et al.*, 2020). The species uses the corners and crevices of buildings to build their shelters and lay their eggs (JACKSON & MACNAB, 1989; MONDAL *et al.*, 2020).

Menemerus bivittatus (Dufour, 1831)

(Figs 7–12; 32)

Salicus bivittatus DUFOUR, 1831:369.

Menemerus bivittatus: PECKHAM & PECKHAM, 1886:292.

(Check other synonyms in WORLD SPIDER CATALOG, 2022).

Diagnosis. *Menemerus bivittatus* differs from the other synanthropic species for having a dorsoventrally flattened body and for the two marginal stripes that run along the entire length of the body (Figs 7, 8). Males and females can be confused with *Menemerus nigli*, due to the dorsoventrally flattened body shape, however, males of *M. bivittatus* differ by not having a curvature of the embolus in the palp (Figs 9, 10). Females of *M. bivittatus* differ in having an epigynum with a large anterior atrium, short median septum, and short copulation ducts (Figs 11, 12).

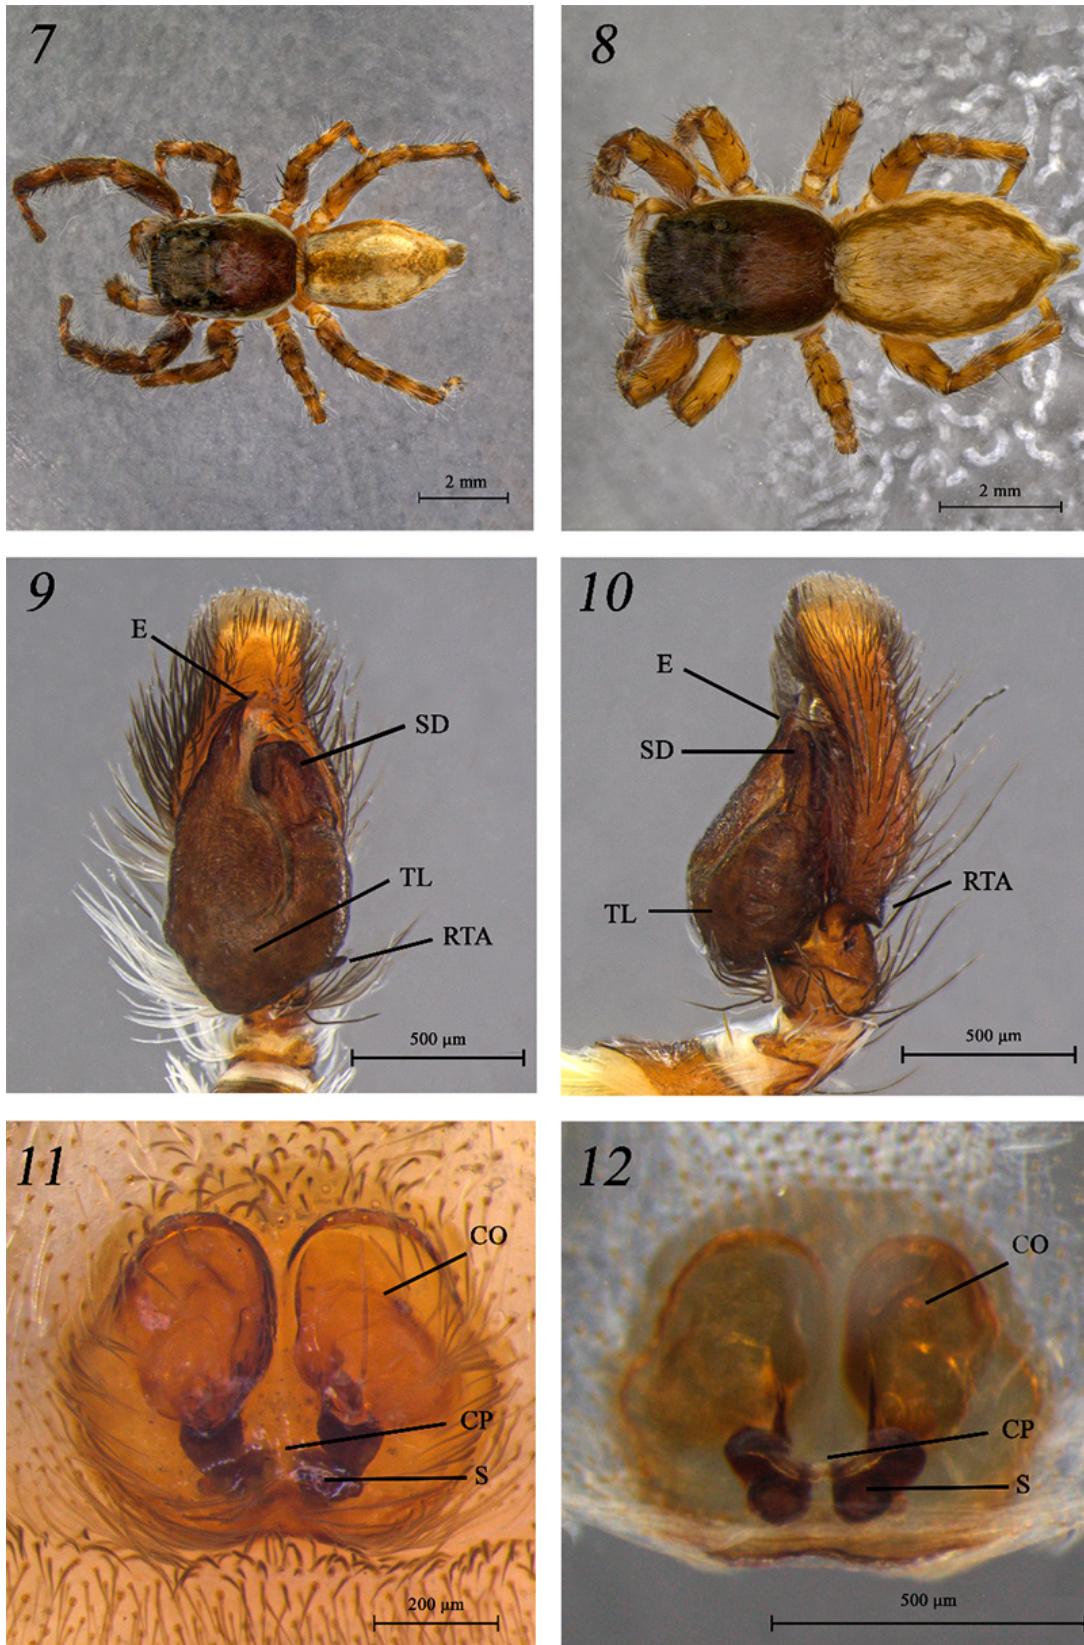

Records in the World. *Menemerus bivittatus* is an African species introduced by anthropic action in southern Europe, China, Taiwan, Japan, Australia, Pacific islands, and the Americas (WORLD SPIDER CATALOG, 2022).

Natural history. The species was popularly named “Saltique à deux raies” (Jumping-spider-two-stripes) (DUFOUR, 1831), and is a synanthropic and cosmopolitan species (WESOŁOWSKA, 1999; RICHARDSON, 2016). Records in Brazilian zoological collections (Fig. 32) indicate that the species occurs only in urban environments, with 83 records in buildings (e.g. sheds, churches, and other commercial

constructions, etc.), fourteen registered in walls, twelve in tree trunks, and seven in beehives (Tab. I).

In their natural environment, they prefer tree trunks (PENNEY & GABRIEL, 2009), feeding on flies, ants, and spiders (MONDAL *et al.*, 2020), but have preference by preying on Meliponini (stingless bees) individuals (PENNEY & GABRIEL, 2009). In Brazil, *M. bivittatus* was recorded preying on pupae of *Camponotus crassus* Mayr, 1862 (Carpenter ants) that were being transported by the ants (HALFELD, 2015).

Menemerus nigli Wesolowska & Freudenschuss, 2012

(Figs 13–18; 34)

Menemerus nigli WESOLOWSKA & FREUDENSCHUSS, 2012: 449, figs 1–6.

Diagnosis. *Menemerus nigli* differs from *M. bivittatus* by presenting a white marginal stripe, however thinner and does not extend to the abdomen (Figs 13, 14). Males have a marked curvature of the embolus in the palp (Figs 15, 16) and females have a pyramid-shaped epigynum, with a shorter anterior atrium, and a short median septum (Figs 17, 18).

Records in the World. *Menemerus nigli* is a newly described species originally from Pakistan; its distribution extends to India and Thailand (WORLD SPIDER CATALOG, 2022), and was recently registered in Brazil (MARIANTE & HILL, 2020) (Fig. 34).

Natural history. In its natural habitat the species is found under rocks (CHATTERJEE *et al.*, 2017), but in urban areas, it is found inside buildings, external walls, and stucco (MARIANTE & HILL, 2020).

Material examined. BRAZIL, Rio de Janeiro: Rio de Janeiro, Bairro de Manguinhos, campus of Instituto Oswaldo Cruz (22°52'19.7"S; 43°14'54.2"W), ♂, ♀, (UFRJ 1634); ♂, ♀ (UFRJ 1636); all collected on II.2020; ♂, ♀ (IBSP 282916); ♀, 1 juv. (IBSP 282916) all collected on VII.2021 by R. M. Mariante col.

Hasarius adansonii (Audouin, 1826)

(Figs 19–24; 33)

Attus adansonii AUDOUIN, 1826:404, plate 7, fig. 8.

Plexippus adansonii: SIMON, 1868:644, plate 2, fig. 12; plates 3, fig. 3.

Hasarius adansonii: SIMON, 1871:330.

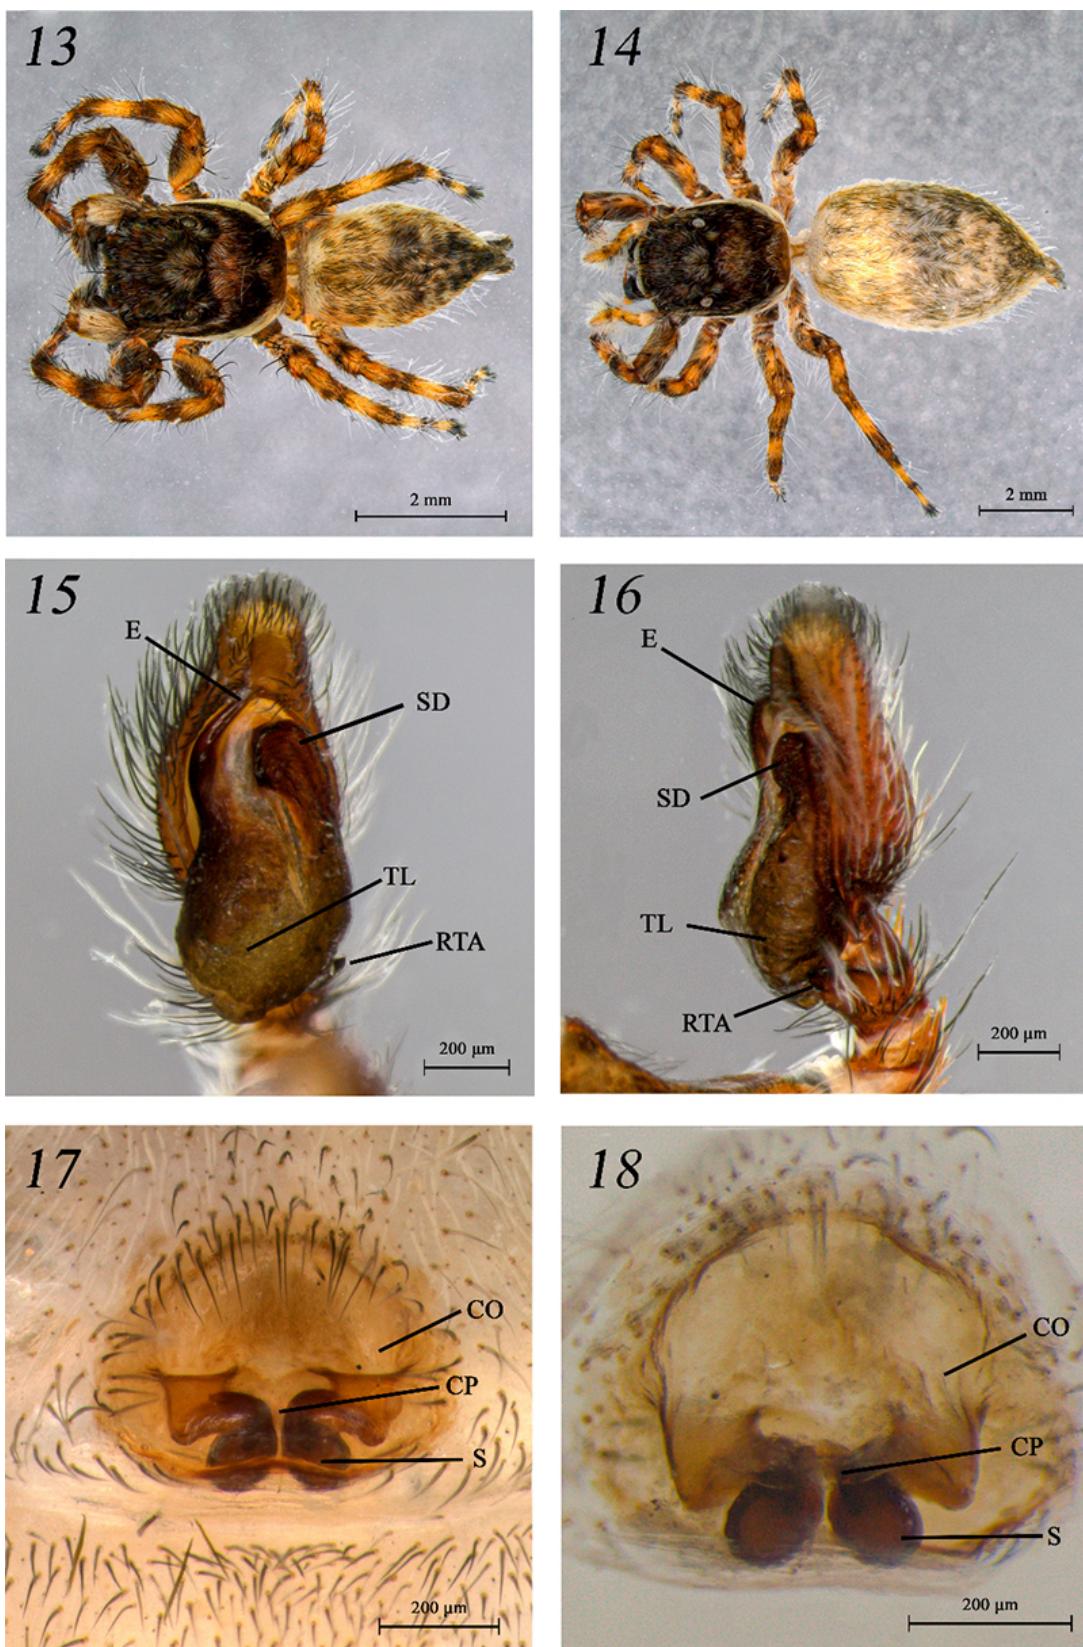

(Check other synonyms in WORLD SPIDER CATALOG, 2022).

Diagnosis. *Hasarius adansonii* differs from other synanthropic exotic Salticidae species in that it has a white arc-shaped band on the posterior area of the cephalothorax and three clear spots on the abdomen, one on the anterior part of the arc-shaped abdomen and two spots on the dorsal part (Figs 19, 20). In the frontal view of the tegulum, the spermatheca duct presents a curvature, with the convex side up. Short, robust, triangular-shaped embolus (Figs 21, 22). The female differs from the other species in having a simple and small epigynum, with sclerotized copulatory openings (Figs 23, 24).

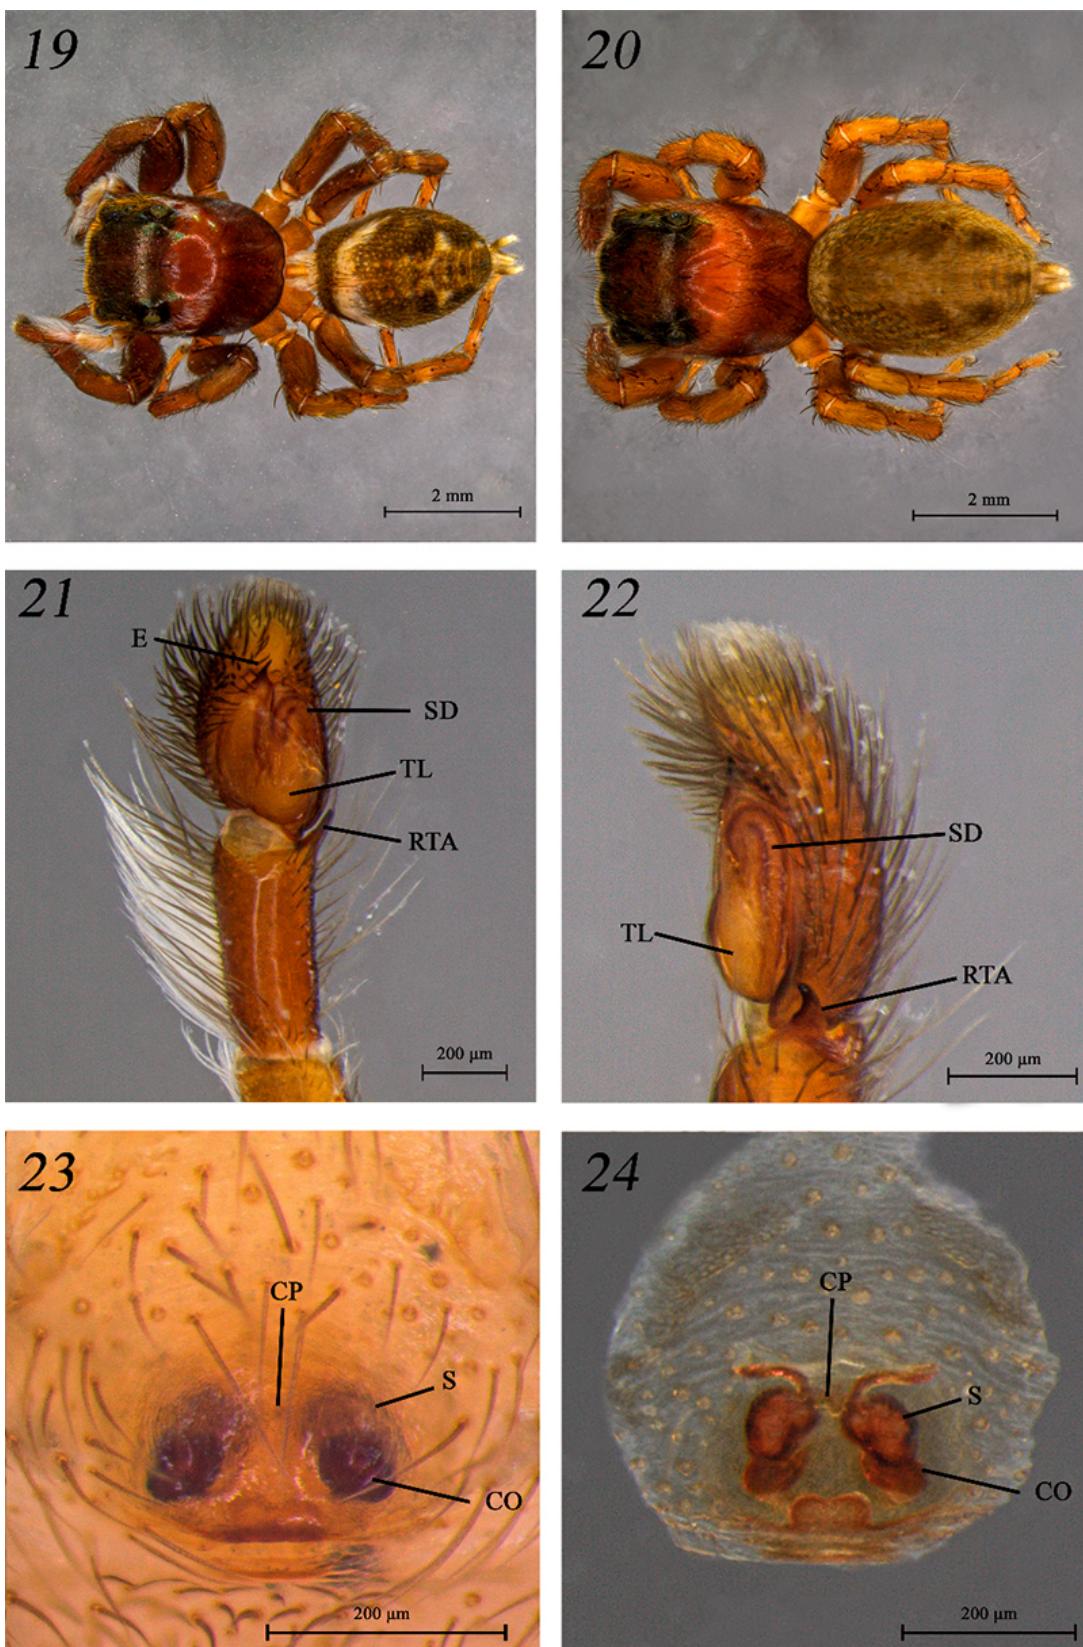

Records in the World. *Hasarius adansonii* is a species native to Africa and the Middle East and has been introduced in Europe, India, Laos, Vietnam, China, Taiwan, Japan, Australia, the Pacific Islands, and the Americas (WORLD SPIDER CATALOG, 2022).

Natural history. Records in Brazilian zoological collections (Fig. 33) indicate that in Brazil the species occurs in an urban environment, being 132 records in urban regions, of these, 68 records in housing and 42 records in other buildings (e.g. sheds and other commercial constructions, etc.) (Tab. I). In the literature, the species is found on external walls, gardens, buildings, shrubs, and around forests (CLARK & BENOIT, 1977; MONDAL *et al.*, 2020), where they deposit their cream-colored eggsac and build shelters up to twice their size (MONDAL *et al.*, 2020).

Material examinado. BRAZIL, Pará: Ilha de Marajó, Soure (00°42'57"S; 48°31'02"W), 2♂ 6♀, 27–28.IX.2016, A. D. Brescovit & A. B. Bonaldo col. Thyene coccineovittata (Simon, 1886)

(Figs 25–30; 34)

Hyllus coccineovittatus SIMON, 1886:348.

Thyene coccineovittata BERLAND & MILLOT, 1941:371; 373, figs 70,71;

HILL & MARIANTE, 2019:2, figs 1–4.

(Check other synonyms in WORLD SPIDER CATALOG, 2022).

Diagnosis. *Thyene coccineovittata* differs from the other synanthropic Salticidae by its more orange and vibrant color, and by the abdomen decorated with two white lateral stripes and one centralized (Figs 25, 26). Males have a long spiral-shaped embolus around the tegulum (Figs 27, 28) and the female differs from the other species in having a simple epigynum, with copulatory openings that are not very sclerotized and long spermatic ducts (Figs. 29, 30).

Records in the World. *Thyene coccineovittata* is a species of African origin (BERLAND & MILLOT, 1941; WORLD SPIDER CATALOG, 2022), which was accidentally introduced in France (OGER & VAN KEER, 2017) and Brazil (Fig. 34) (MARIANTE & HILL, 2018).

Natural history. *Thyene coccineovittata* is the synanthropic exotic Salticidae in Brazil with more striking coloration, is commonly found in vegetation (DIPPENAAR-SCHOEMAN *et al.*, 2005), Brazil it was recorded in *Triplaris* sp. (Polygonaceae) (MARIANTE & HILL, 2018), the species is an efficient insect predator (DIPPENAAR-SCHOEMAN *et al.*, 2005; MONDAL *et al.*, 2020) and has been recorded feeding on insect Pentatomidae eggs (CUKIER, 2020).

Material examinado. BRAZIL, **Rio de Janeiro:** Rio de Janeiro, Bairro Vargem Pequena (22°59'21.1"S; 43°27'55.7"W), ♂, ♀, 12.IV.2019, R. M. Mariante col. (UFRJ 1633); ♀, 24.IV.2019, R. M. Mariante col. (UFRJ 1635); ♂, 11.VII.2021, R. M. Mariante col. (UFRJ 1635 A).

The environment of synanthropic exotic Salticidae. From the date of the zoological collections examined, 647 records were obtained, containing 1118 individuals, being 633 females, 446 males, and 39 juveniles. *Hasarius adansoni* was the species with the highest number of records in the collections (258), followed by *Plexippus paykulli* (196), and *Menemerus bivittatus* (186), *Menemerus nigli* (4), and *Thyene coccineovittata* (3). Of these, 363 (56%) had additional information regarding the collections (e.g. collected indoors, on walls, vegetation, etc.). *Plexippus paykulli* had 97 (49%) records with collection observations, *M. bivittatus* 120 (65%) and *H. adansoni* 139 (54%) (Tab. I), the four records of *M. nigli* are from collections in urban buildings and *T. coccineovittata* presented three records associated with urban vegetation.

The distribution of synanthropic exotic Salticidae. Three of the five species have a wide distribution in Brazil, where *Plexippus paykulli* occurs in 22 of the 27 federative units, being absent in Alagoas, Amapá, Distrito Federal, Pernambuco, and Rondônia (Fig. 30).

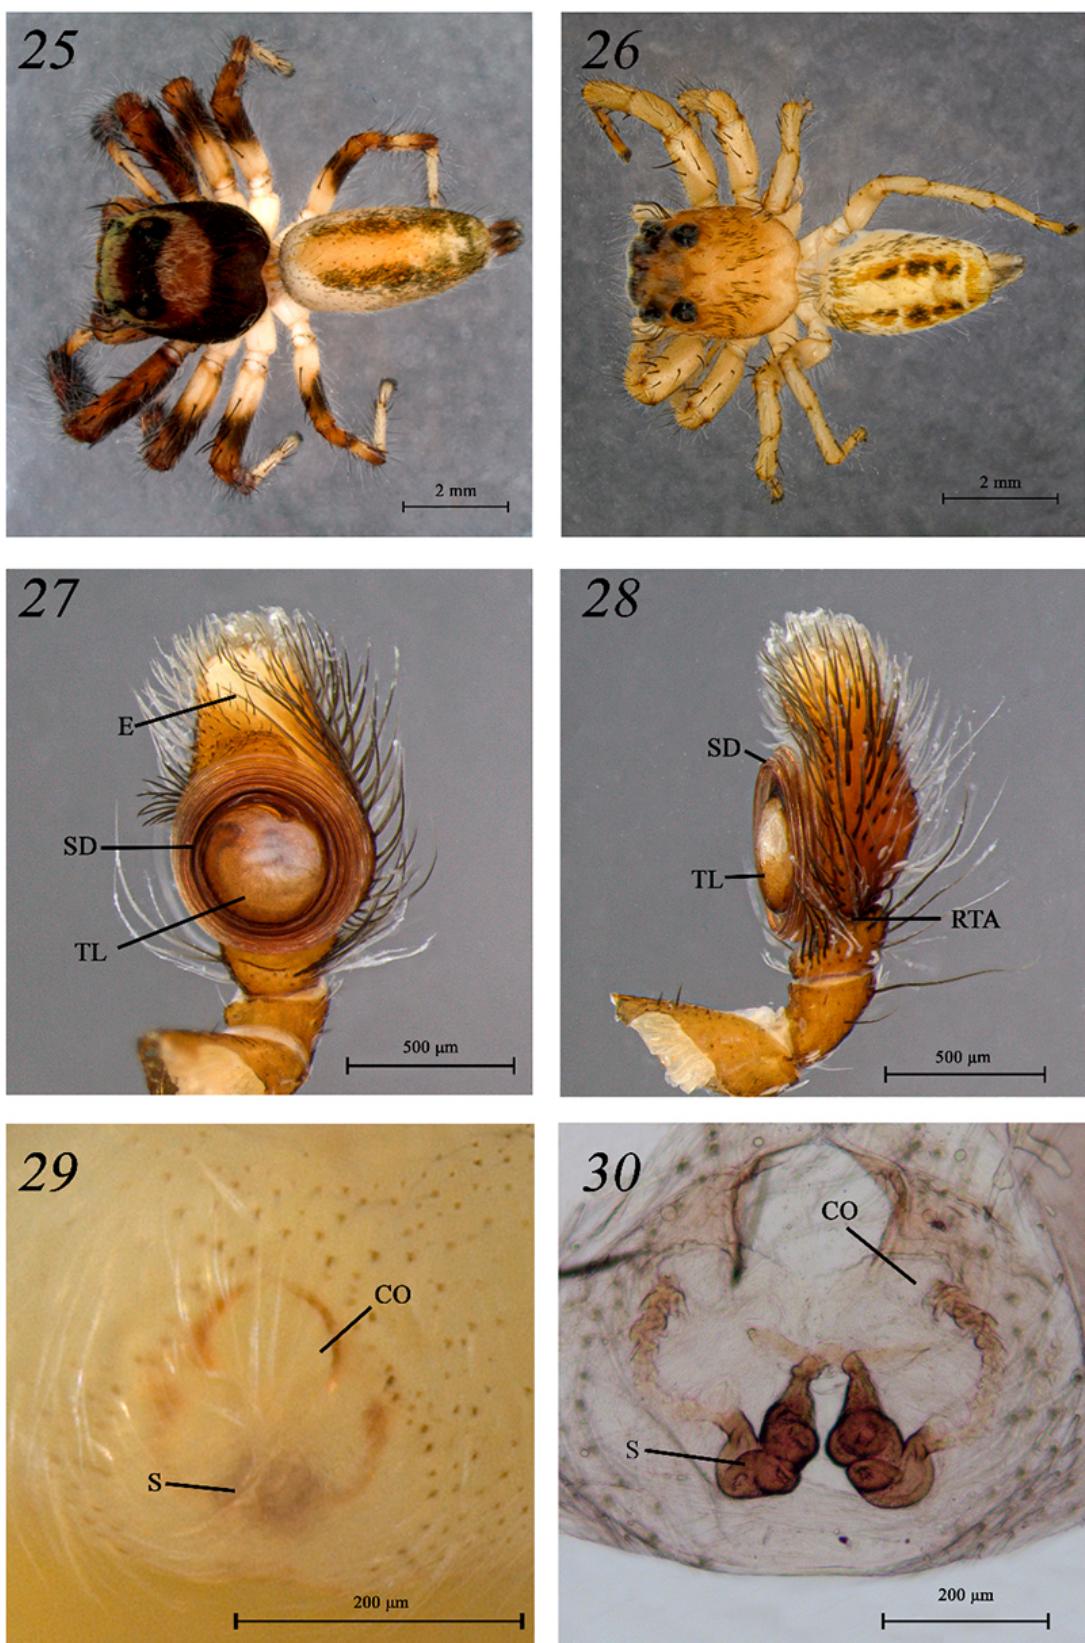

Menemerus bivittatus occurs in 19 states, being absent in Amapá, Ceará, Distrito Federal, Goiás, Maranhão, Paraíba, Rondônia and Roraima (Fig. 32).

Hasarius adansoni occurs in 17 states, being absent in Acre, Alagoas, Amapá, Amazonas, Ceará, Distrito Federal, Paraíba, Rio Grande do Norte, Rondônia and Roraima (Fig. 32).

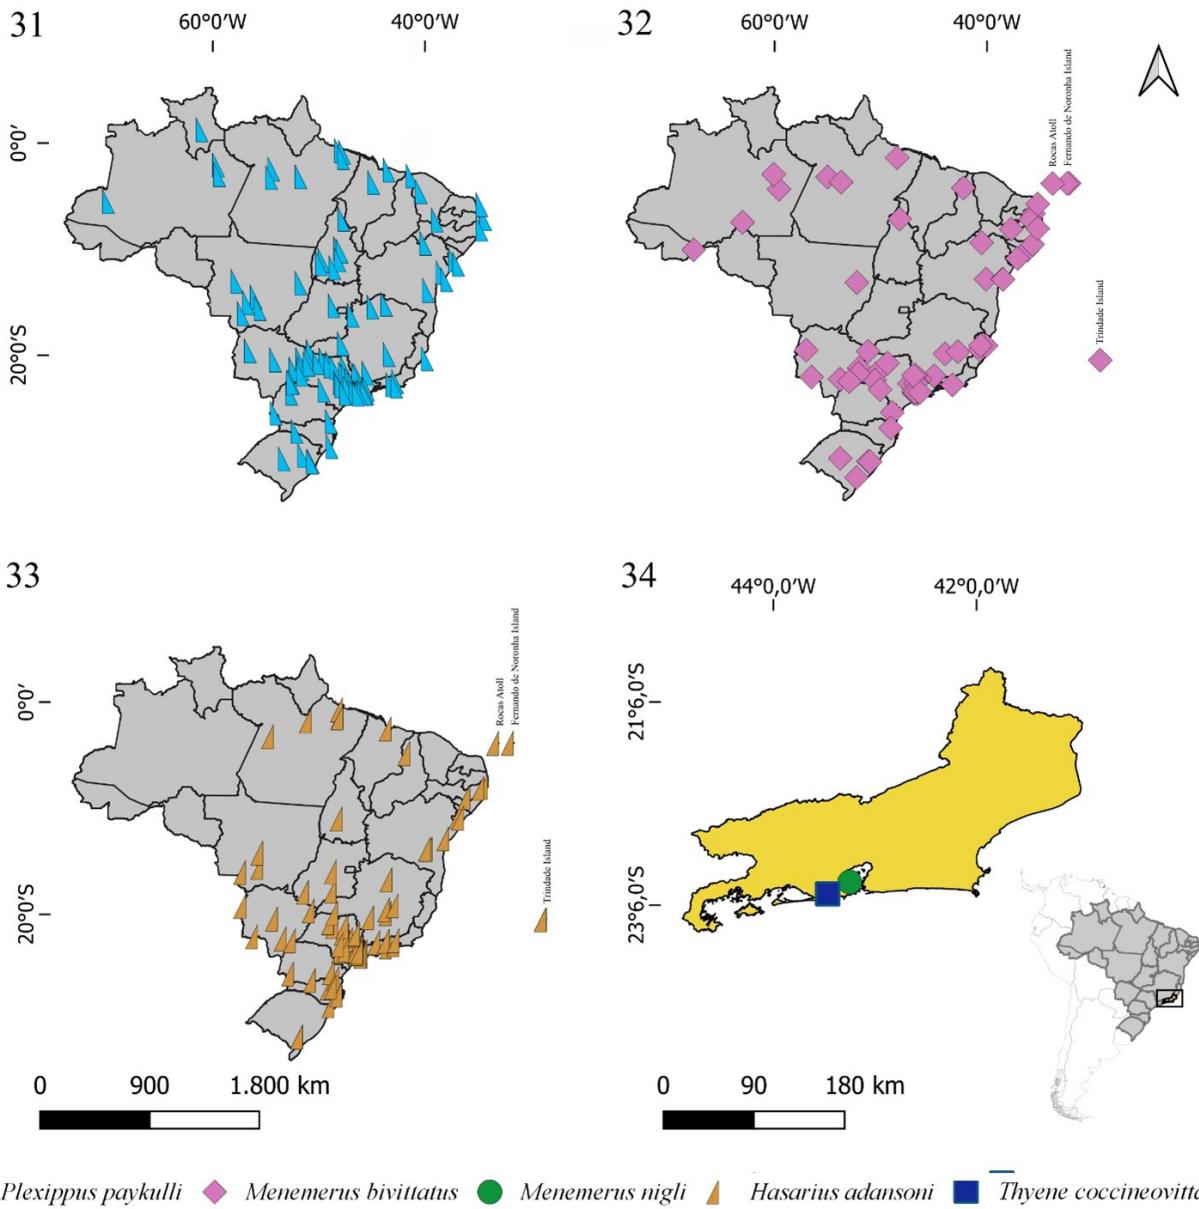

Menemerus nigli and *Thyene coccineovittata* in Brazil were only recorded in the city of Rio de Janeiro (Fig. 34).

Currently, Brazil has only five species of exotic Salticidae. The introduction of *M. bivittatus* and *H. adansoni* it has first recorded in the year 1924 in Blumenau, Santa Catarina; *P. paykulli* was registered for the first time in the year 1934 in Porto Alegre, Rio Grande do Sul.

Plexippus paykulli was the species that showed greatest restriction to anthropized areas, with 94 records associated with human constructions and two records related with urban vegetation; this information corroborates the existing

Figs 25–30. *Thyene coccineovittata* (Simon, 1886) (25, 27, 28: ♂; 26, 29, 30: ♀). Figs. 25, 26, habitus, dorsal view; 27, palp, ventral view; 28, palp, retrolateral view; 29, epigynum, ventral view; 30, epigynum, dorsal view (CO, copulatory opening; E, embolus; RTA, retrolateral tibial apophysis; S, spermatheca; SD, sperm duct; TL, tegular lobe). Fig. 30 was used with the permission of Dr. David Hill and Dr. Rafael.

Figs 31–34 Distribution map of alien synanthropic species of Salticidae in Brazil: 31, *Plexippus paykulli* (Audouin, 1826); 32, *Menemerus bivittatus* (Dufour, 1831); 33, *Hasarius adansoni* (Audouin, 1826); 34, *Menemerus nigli* Wesolowska & Freudenschuss, 2012 and *Thyene coccineovittata* (Simon, 1886).

literature (JACKSON & MACNAB, 1989; MONDAL *et al.*, 2020), the only record in which the plant was identified, is from a collection carried out in *Digitaria horizontalis* (Jamaican crabgrass). The greater number of records associated with human constructions may be linked to the fact that the species uses the corners of buildings to build their refuges (JACKSON & MACNAB, 1989; MONDAL *et al.*, 2020).

Menemerus bivittatus has 95 records associated with human constructions (mainly on walls) and 16 related with urban vegetation (mainly on tree trunks), corroborating the existing literature (WESOŁOWSKA, 1999; PENNEY & GABRIEL,

2009; MONDAL *et al.*, 2020). However, the higher occurrence in anthropized regions may indicate a preference for urban niches in regions where the species was introduced. Beyond these, five records are associated with the hive of bees in São Paulo, São Paulo, and the one record is related with the hive of *Trypoxylon* sp. (wasp) in the region of Botucatu, São Paulo.

Hasarius adansoni has the greater diversity of occupied niches, with 108 records in human constructions and 16 records related with urban vegetation, of this, only one in a tree trunk; this information corroborates the existing

Tab. I. Number of records per observation of the collection site of the most representative species of synanthropic exotic Salticidae.

Collection location	<i>Plexippus paykulli</i>	<i>Menemerus bivittatus</i>	<i>Hasarius adansoni</i>
Dwellings	74	46	68
Edification	10	26	32

Total	196	186	258

literature, where the species is commonly reported in the peridomicile of residences (CLARK & BENOIT, 1977; MONDAL *et al.*, 2020).

Menemerus nigli was only found in anthropized areas, but the presence of another species of the same genus allows us to speculate that it will have the same distribution profile and occupy the same niches.

The records of *T. coccineovittata* in urban vegetation may indicate that this Salticidae prefers environments such as gardens, urban parks, woods, and forests. If the species starts to occupy natural niches, it could pose a threat to arthropod populations and their ecosystem relationships. More studies are need on its invasive potential and its impact on ecosystems.

Menemerus nigli and *Thyene coccineovittata* have a restricted distribution in the city of Rio de Janeiro – Rio de Janeiro, probably due to the recent introductions of the species. *Plexippus paykulli*, *M. bivittatus*, and *Hasarius adansoni* are widely distributed throughout Brazil, and the regions where no records were found are likely related to the lack of collections.

Although *M. bivittatus* occurs in urban áreas and probably does not impact most other species, further studies are needed to understand whether the species may be impacting native bee populations. Already *P. paykulli* and *H. adansoni* do not affect native species and they occur together with synanthropic native Salticidae in urban niches such as *Megafreya sutrix* (Holmberg, 1875) and *Frigga quintensis* (Tullgren, 1905).

In addition, in the Americas, there are species of exotic *Menemerus* and may result in new introductions *M. brachygynathus* (Thorell, 1887), *M. taeniatius* (L. Koch, 1867), *M. semilimbatus* (Hahn, 1829). Although the literature indicates two species of *Hasarius* for Brazil, *Hasarius lisei*

needs a taxonomic review, since its structures do not match the diagnosis of the genus.

Acknowledgments. Francisco Luís Franco for the review and suggestions. To the curators of the collections mentioned in the text for making the materials examined in this study available. David Edwin Hill, Rafael Meyer Mariante and Flavio Yamamoto for loaning the photos. This study was possible thanks to a scholarship provided by the *Centro de Formação de Recursos Humanos para o SUS/SP “Doutor Antônio Guilherme de Souza”* in partnership with *Instituto Butantan*.
