BORBA, R.S., SILVA, E.L., PONZETTO, J.M., POZZOBON, A.P.B., CENTOFANTE, L., ALVES, A.L. & PARISE-MALTEMPI, P.P. **Genetic structure of the ornamental tetra fish species *Piabucus melanostomus* Holmberg, 1891 (CHARACIDAE, IGUANODECTINAE) in the Brazilian Pantanal wetlands inferred by mitochondrial DNA sequences.** Biota Neotrop. 13(1): <http://www.biotaneotropica.org.br/v13n1/en/abstract?article+bn00413012013>

**Abstract:** The subfamily Iguanodectinae comprises a group of small Neotropical fishes composed by two genera and 11 nominal species widely distributed in the Atlantic drainages of South America. *Piabucus* is the only genus of Iguanodectinae found in the Paraguay River basin, especially in the Pantanal of Mato Grosso State, where it is represented by *Piabucus melanostomus*. Given the wide distribution and the low dispersion capacity of this species, due to the ecological constraints, it is possible that many interesting genetic features could be found in different populations. In this way, the aim of his work was to perform the phylogeographic pattern of *P. melanostomus* populations using mitochondrial DNA sequences. A total of 13 individuals from three rivers belonging the Mato Grosso wetland were sampled. The ATP sintetase (subunits 6 and 8) gene was completely sequenced, the mean of nucleotide base composition in the sequences was 31.2% (T), 30.2% (C), 26.9% (A) and 11.9% (G), with no gene saturation. The population analysis in the TCS program generated a network with six haplotypes (A to F), where the ancestral haplotype (A) has a frequency of 25% and is composed by individuals from Cuiabá and Paraguay Rivers. The phylogenetic analysis showed the occurrence of two mtDNA lineages (1 and 2), the distance observed between the two lineages was 0.6%. The phylogenetic and phylogeographic results as well as the negative values of *Fst* for some populations, indicate a possible occurrence of gene flow among the analyzed populations. These results highlights the importance of flood pulse existent on wetland as a vehicle that permits a temporary connection among isolated population maintaining the species genetic variability.

**Keywords:** flood pulse, genetic diversity, gene flow, haplotypes.

BORBA, R.S., SILVA, E.L., PONZETTO, J.M., POZZOBON, A.P.B., CENTOFANTE, L., ALVES, A. L. & PARISE-MALTEMPI, P.P. **Estrutura genética da espécie de peixe ornamental tetra *Piabucus melanostomus* Holmberg, 1891 (CHARACIDAE, IGUANODECTINAE) do Pantanal brasileiro inferida por sequências de DNA mitocondrial.** Biota Neotrop. 13(1): <http://www.biotaneotropica.org.br/v13n1/pt/abstract?article+bn00413012013>

**Resumo:** A subfamília Iguanodectinae compreende um grupo de pequenos peixes neotropicais composta de dois gêneros e 11 espécies nominais amplamente distribuídas nas bacias dos rios Paraguai e Atlântico Sul. *Piabucus* é o único gênero de Iguanodectinae encontrado na bacia do rio Paraguai, especialmente no Pantanal de Mato Grosso, onde é representada por *Piabucus melanostomus*. Dada a ampla distribuição e a baixa capacidade de dispersão desta espécie, devido às limitações ecológicas, é possível que características genéticas interessantes possam ser encontradas em diferentes populações. Desta forma, o objetivo deste trabalho foi estabelecer os padrões filogeográficos de populações de *P. melanostomus* utilizando sequências de DNA mitocondrial. Foram amostrados 13 indivíduos de três rios pertencentes ao Pantanal do Mato Grosso. O gene ATP sintetase (subunidades 6 e 8) foi completamente sequenciado, a média da composição de base de nucleotídeos nas sequências foi de 31,2% (T), 30,2% (C), 26,9% (A) e 11,9% (G), não havendo saturação. A análise populacional no programa TCS gerou uma rede com seis haplótipos (A a F), onde o haplótipo ancestral (A) tem uma freqüência de 25% e é composto por indivíduos dos rios Cuiabá e Paraguai. A análise filogenética mostrou a ocorrência de duas linhagens de DNA

(1 e 2), a distância observada entre as duas linhagens foi de 0,6%. Os resultados filogenéticos e filogeográficos, bem como os valores negativos de FST para algumas populações, indicam uma possível ocorrência de fluxo de genes entre as populações analisadas. Estes resultados destacam a importância do pulso de inundação existente em zonas úmidas como um veículo que permite uma conexão temporária entre a população isolada, mantendo a variabilidade genética das espécies.

**Palavras-chave:** *pulso de inundação, divergência genética, fluxo gênico, haplótipos.*

## Introduction

Iguanodectinae is a small characid subfamily composed by 11 nominal species in two genera: *Iguanodectes* (Cope 1872) and *Piabucus* (Oken 1817). It is comprised by fishes with elongated bodies basally-contracted, multicuspid teeth, gill-membranes united and free from the isthmus, and the genera are distinguished by the presence of a long pectoral fin, and a well-developed pectoral keel (Moreira 2003). These fishes are distributed in the Amazon (including its main tributaries), Orinoco, Paraguay, and Tocantins River basins, as well as the coastal drainages from the Gulf of Pára (Venezuela) to immediately south of the mouth of the Amazon River (Vari 1977).

The Pantanal wetland corresponds to an extensive alluvial plain drained by the Paraguay River and its tributaries, one of the largest sedimentary plains of the globe. This region is subject to seasonal flooding that vary in intensity, extent and permanence (Silva & Abdón 1998, Silva 2002). The area covered and the predominance of the flood pulse dictate the availability of habitats and food for fish, crustaceans, birds, reptiles, mammals, aquatic plants and semi-aquatic, conditioning their abundance and their reproductive behavior (Bonetto et al. 1981, Catella 1992, Cordiviola de Yuan 1992, Junk & Bayley 1989, Campos 1991, Mauro 1993).

This phenomenon is one of the factors governing the local biodiversity, favoring animal and vegetal species related to both flood and drought (Calheiros & Ferreira 1997). Alternatively, the presence of temporary lakes can isolate populations during certain time, and also put together another one favoring the gene flow among these populations. Due to these characteristics, this system is considered one resource of the biodiversity and fresh water of the planet due of their importance and their exposure to environmental threats (Gonçalves et al. 2011).

The *Piabucus* is the only genus of Iguanodectinae found in the Paraguay River basin, mainly in Pantanal of Mato Grosso, and the only species occurring in this region is *Piabucus melanostomus* (Britski et al. 2007) (Figure 1). This is an omnivorous species, feeding on higher plants, algae, invertebrates, and detritus, inhabits lentic water bodies formed by the temporary overflow of major rivers and generally is associated with macrophytes that provide food and shelter (Pereira & Almeida 1998). However, the other biological aspects of this species are very scarce. The *Piabucus* species are the largest used as ornamental fish in Brazil and other countries, and are representative of the fishes group called “tetra”.

Genetic studies in Iguanodectinae are very limited, so that studies concerning phylogenetic and phylogeographic relationships

of species and populations belong to the subfamily are nonexistent. Published data only includes details of the haploid number ( $n = 25$ ) in *Iguanodectes spilurus* Günther, 1864 (Scheel 1973), estimates of nuclear DNA content for *P. melanostomus* (Carvalho et al. 2002) and a recent cytogenetic characterization in *P. melanostomus* (Silva et al. 2011), the subject of this study.

The wide distribution and low dispersion capacity of *P. melanostomus* associated with the water dynamic in the Pantanal wetland region may represent an interesting model of local phylogeographic study. In this study it was analyzed the mitochondrial DNA sequences from individuals of *P. melanostomus* aiming to observe the existence of genetic variations among populations found in the wetland region related to gene flow and discuss the results based on the influence of the flood pulse characteristic of this region.

## Materials and Methods

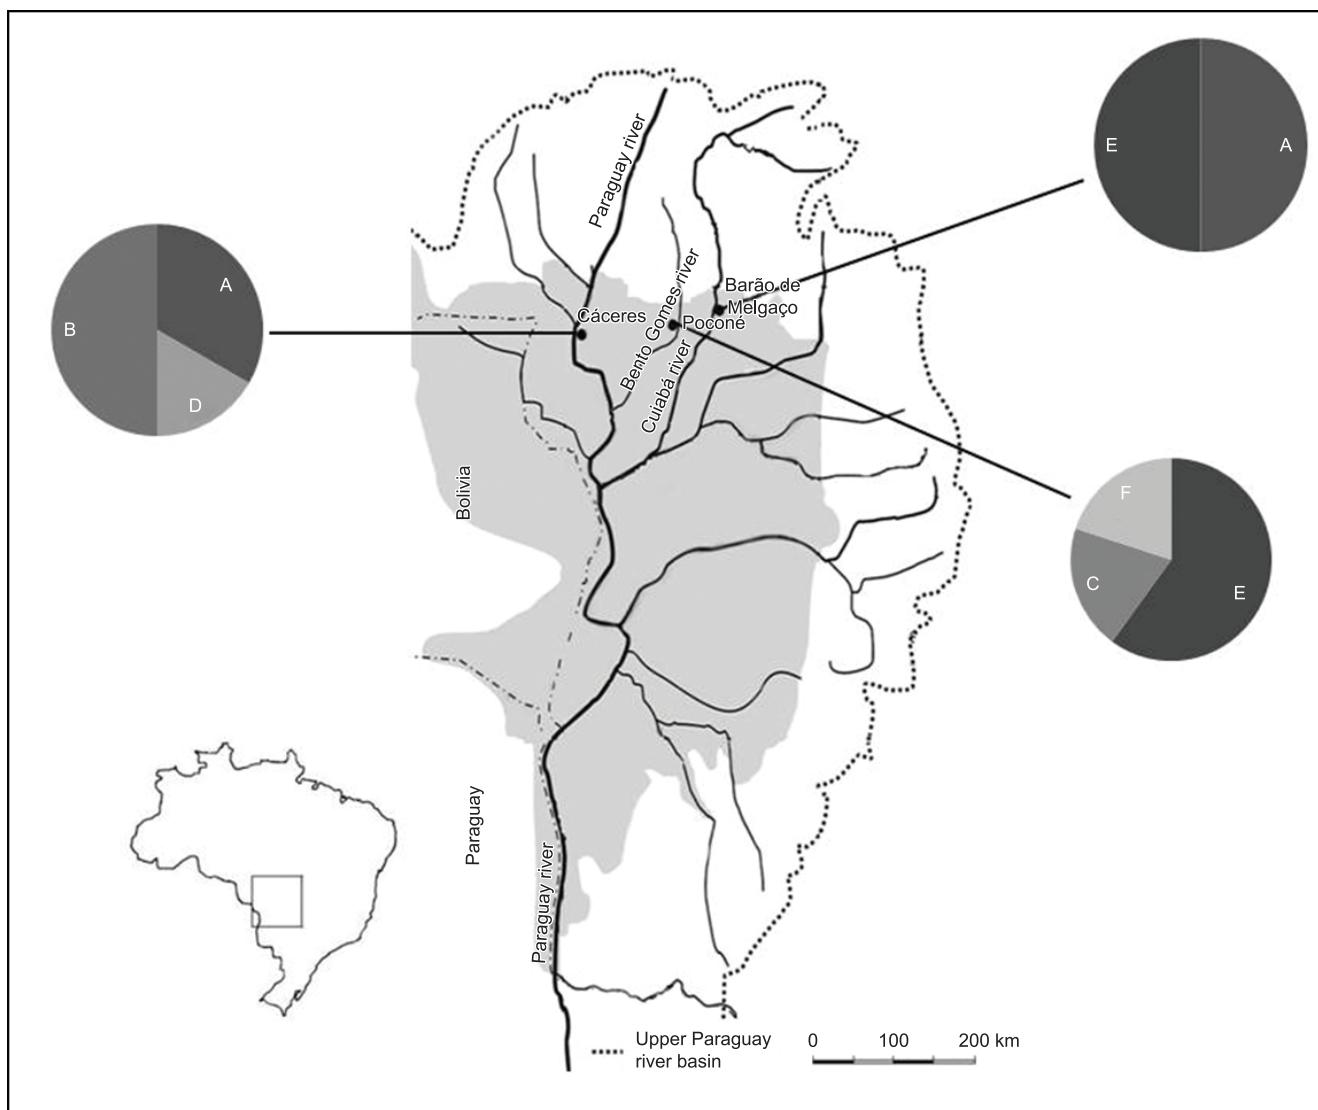

A total of 13 individuals of *Piabucus melanostomus* from three rivers of the Mato Grosso wetland (Figure 2) were sampled: Bento Gomes River (5 individuals), Cuiabá River (2 individuals) and Paraguay River (6 individuals) (Table 1). *Astyanax fasciatus*, *A. bockmani* and *A. paranae* from Paraná River basin were used as outgroup. The specimens were deposited in the ichthyological collection of Laboratório de Citogenética, Universidade Estadual Paulista (UNESP, Rio Claro, Brazil).

DNA was extracted with the phenol-chloroform-isoamyl alcohol technique (Sambrook & Russell 2001). PCR amplification of the ATPase 6/8 gene region was obtained from a volume of 13.5 mL of a solution containing 6.25 mL of PCR Mix (Qiagen), 5.25 mL of Milli Q water, 0.5  $\mu$ L primer F (10  $\mu$ M), 0.5 mL of primer R (10  $\mu$ M) and 1.0 mL of template DNA (200 ng). PCR was performed in a thermocycler (Eppendorf Mastercycler) and consisted of the following cycling conditions: an initial cycle of denaturation at 94 °C for 40 s, followed by 35 cycles at 94 °C for 30 s, annealing at 55 °C for 40 s, chain extension at 68°C check temperature extension for 2 minutes, and a final extension at 72 °C for 5 minutes. The following set of primers was used: L8331 (5'-AA GCR TYR GCC TTT TAA GC-3') and H9236 (5'-GTT AGT GGT CAK GGG CTT GGR TC-3') (Perdices et al. 2002). The amplified DNA segments were run on 1% agarose gel and visualized in ultraviolet light. The quantification of the amplified gene products was performed using the molecular weight marker Lambda ( $\lambda$ ) DNA 50 ng and 30 ng. For the sequence analysis, the amplified DNA was purified with the EXOSAP enzyme and subsequently sequenced (MacroGen, Korea).

The saturation analysis of data was performed using the Dambe 4.5.8 (Xia & Xie 2001) by plotting the transitions (s) and transversions (v) against genetic divergence estimated by the model of sequence evolution “Felsenstein 84.”Model Test 3.06 (Posada & Crandall 1998) was used to find the best fitting evolution model for our data. The model selected by the Akaike criterion was GTR+I+G (empirical base frequencies A=0.3338, C=0.3053, G=0.1023, T=0.2586; substitution rates: A-C=1.77, A-G=36.7617, A-T=0.5967, C-G=2.1775, C-T=17.2043, G-T=1.0). These parameters were used to estimate Maximum Likelihood (ML) distances in the Neighbor-

| Paraguay 4      | Paraguay | Paraguay river    | B         | 1             |
| Paraguay 5      | Paraguay | Paraguay river    | B         | 1             |
| Paraguay 6      | Paraguay | Paraguay river    | B         | 1             |
| Bento 1         | Paraguay | Bento Gomes river | E         | 2             |
| Bento 2         | Paraguay | Bento Gomes river | C         | 1             |
| Bento 3         | Paraguay | Bento Gomes river | E         | 2             |
| Bento 4         | Paraguay | Bento Gomes river | E         | 2             |
| Bento 6         | Paraguay | Bento Gomes river | F         | 2             |
| Cuiabá 1        | Paraguay | Cuiabá river      | A         | 1             |
| Cuiabá 2        | Paraguay | Cuiabá river      | E         | 2             |

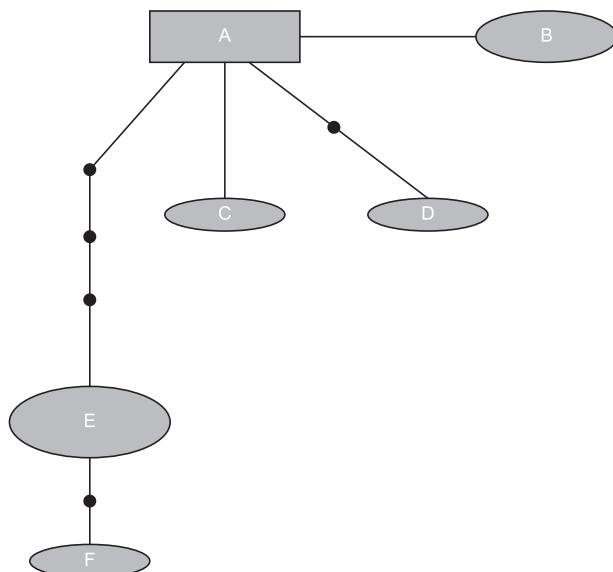

Joining (NJ) analyses in PAUP\*, with 1,000 bootstrap replicates. The maximum parsimony (MP) analysis was performed using heuristic searches with tree-bisection-reconnection (TBR) branch swapping and 10 random-taxon-addition replicates.

To evaluate the association among haplotypes and their geographical distribution the program TCS v1.21 was used, this program uses statistical parsimony (Clement et al. 2000). The genetic structure of populations was measured by *Fst* values with the aid of ARLEQUIN 3.11 (Excoffier et al. 2005).

## Results and Discussion

The alignment of the ATPase 6/8 gene sequences revealed 834 conserved and 9 variable base pairs, of which 5 were informative for the Maximum Parsimony analysis. The mean of nucleotide base composition in the sequences was 31.2% (T), 30.2% (C), 26.9% (A) and 11.9% (G), with no gene saturation.

The population analysis in the TCS program generated a network with six haplotypes (A to F), where the ancestral haplotype (A) has a frequency of 25% and is composed by individuals from Cuiabá and Paraguay Rivers. The haplotype “E” is the most frequent (33.3%) and is composed by individuals from Bento Gomes and Cuiabá Rivers. The remaining individuals are distributed in haplotypes B, C, D and F (see Table 1). The haplotype sharing event was observed in “A” with Cuiabá and Paraguay populations and “E” with Bento Gomes and Cuiabá populations (Figure 3) (Table 1).

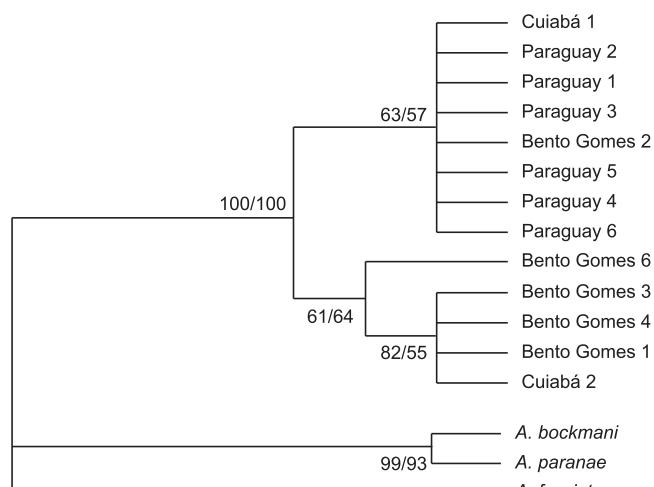

**Figure 3.** Haplotype network performed through TCS program.

The sharing of haplotypes A and E in the Cuiabá River can be associated with historical and seasonal events. Specifically in the case of the E haplotype the sharing can be explained by the temporary union in the flood season from Bento Gomes and Cuiabá Rivers due to their proximity. The presence of the haplotype shared between the Paraguay and Cuiabá Rivers can be considered derived from an ancient gene flow mainly by the large geographical distance between these two points. The Cuiabá River is considered one of the most important tributaries of the Paraguay River and has its mouth located approximately 130 km downstream from the collection point in the Paraguay River. Whereas *P. melanostomus* is a non-migratory species and restricted to environment of slower waters, the own Paraguay River may act as a barrier to gene flow, as already described for the species *Oligosarcos hepsetus* (Centofante et al. 2006).

The phylogenetic analysis showed the occurrence of two mtDNA lineages: The first one (1) with individuals from populations of Paraguay, Bento Gomes and Cuiabá Rivers, and the second (2) with individuals from populations of Bento Gomes and Cuiabá Rivers. The topology of the phylogenetic tree of two methods (NJ and MP) was similar and the variations observed were related to the bootstrap values (Figure 4). The genetic distance performed within mtDNA lineages showed for lineage “1”, 0.1% and for lineage “2”, 0.2%. The distance observed between the two lineages was 0.6%.

The *Fst* (Table 2), phylogenetic and phylogeographic results highlight the presence of gene flow among some populations of *P. melanostomus*. This fact is due to the haplotype sharing between individuals of Paraguay and Cuiabá Rivers and individuals from

**Figure 4.** Phylogenetic tree based on the ATPase 6/8 mitochondrial gene using NJ and MP methods. Numbers on branches represent bootstrap values for NJ, MP.

**Table 2.** *Fst* values of pairs of the sampled population.

|            | Bento 1 | Bento 2 | Cuiabá 1 | Cuiabá 2 | Paraguay 1 | Paraguay 2 |
|------------|---------|---------|----------|----------|------------|------------|
| Bento 1    | 0.00000 | -       | -        | -        | -          | -          |
| Bento 2    | 0.64706 | 0.00000 | -        | -        | -          | -          |
| Cuiabá 1   | 0.25000 | 0.00000 | 0.00000  | -        | -          | -          |

| Paraguay 1 | 0.66667 | 0.20755 | -0.20000 | -0.20000 | 0.00000    | -          |
| Paraguay 2 | 1.00000 | 0.64706 | 0.64706  | 0.64706  | 0.66667    | 0.00000    |

Bento Gomes and Cuiabá Rivers. In addition, the relative low genetic distances observed among populations indicate that the variation in the mitochondrial sequences may be too recent.

Since the Pantanal wetland is characterized by seasonal flood area, in the low water season, the fishes begin to form groups, due to contraction of the environment (Ribeiro & Petre, 1990). For this reason it is possible to find some peculiarities in different populations. Silva et al. (2011) e.g., observed potential NOR chromosome markers for populations of Paraguay River, so it can be suggested that the sharing of haplotypes between individuals of Paraguay and Cuiabá Rivers is due to the same seasonal phenomena. Similarly geomorphologic and climatic events through time have influenced the genetic composition of population in the Rio Negro basin. In this basin Cooke et al. (2009) observed high levels of polymorphism in different populations of *Paracheirodon axelrodi*.

These results highlight the importance of flood pulse existent on wetland as a vehicle that permits a temporary connection among isolated population maintaining the genetic variability.
