Tatia comprises twenty-five valid species, distributed in the main inland watersheds of South America, including the Orinoco, Essequibo, and coastal rivers of Suriname, Amazon, upper rio Paraná and São Francisco basins. A new species is described from tributaries of upper rio Manuel Alves on uplands of Serra Geral do Tocantins plateau, Tocantins State, Brazil. It is promptly distinguished from all congeners, except *Tatia britskii*, due to absence of an adipose fin. It differs from *T. britskii* by the longer caudal peduncle length (24.1–30.5% SL, mean 25.3 vs. 20.0–22.7, mean 20.9); caudal peduncle depth (10.9–16.8 SL, mean 14.1 vs. 9.4–10.5, mean 9.8), and anterior cranial border with mesethmoid width equals its length (vs. width approximately three times its length in *T. britskii*). Additionally, information regarding the poorly known species *Tatia simplex* originally described from rio das Mortes, is provided.

Tatia abriga vinte e cinco espécies válidas distribuídas nos maiores sistemas fluviais de águas interiores da América do Sul, como o Orinoco, Essequibo, e rios costeiros do Suriname, Amazonas, alto Paraná e São Francisco. Uma espécie nova é descrita para tributários do alto rio Manuel Alves, nos contrafortes da Serra Geral do Tocantins, estado do Tocantins, Brasil. A espécie nova é facilmente distinguida de todos os congêneres, exceto *Tatia britskii*, pela ausência de nadadeira adiposa. Difere de *T. britskii* pelo maior comprimento do pedúnculo caudal (24,1–30,5% CP, média 25,3 vs. 20,0–22,7% CP, média 20,9); altura do pedúnculo caudal (10,9–16,8 SL, mean 14,1 vs. 9,4–10,5, mean 9,8) e margem craniana anterior com largura do mesetmoide igual a seu comprimento (vs. largura aproximadamente três vezes no seu comprimento em *T. britskii*). Adicionalmente, são fornecidas informações sobre *Tatia simplex*, uma espécie pouco conhecida, descrita para o rio das Mortes.

INTRODUCTION

Tatia Miranda Ribeiro, 1911 is currently the most species-rich genus in Centromochlinae, comprising twenty-five valid species of small-sized catfish present in all inland South American large drainages east of the Andes, as the Orinoco basin in Venezuela and Colombia, Amazon basin from Ecuador to Brazil, coastal rivers of northern South America between the mouths of the Orinoco and Amazon rivers and upper rio Paraná and São Francisco basins (Soares-Porto, 1998; Ferraris, 2003, 2007; Sarmento-Soares, Buckup, 2005; Akama, Sarmento-Soares, 2007; Sarmento-Soares, Birindelli, 2015; Calegari *et al.*, 2019). The monophyly of the genus is supported by 13 molecular and three non-exclusive morphological synapomorphies: coronomeckelian bone obliquely positioned, hyomandibula and metapterygoid separated from each other, and contralateral anteromedial processes of basipterygium sutured to each other on anterior portion (Calegari *et al.*, 2019).

In the rio Tocantins drainage, *Tatia* is represented by two species, namely: *T. intermedia* (Steindachner, 1877) and *T. simplex* Mees, 1974 (Ferraris, 2007; Sarmento-Soares, Martins-Pinheiro, 2008). *Tatia simplex* is poorly understood taxonomically. Its description was based on a single juvenile specimen (28.5 mm SL) collected in 1968 at rio das Mortes, Mato Grosso State, Brazil. Since its original description by Mees (1974) the species was kept under the name *Centromochlus simplex* in taxonomic lists and catalogues, with geographic distribution reported only to the type locality (*e.g.*, Ferraris, 2003, 2007). No additional material of the species was identified for thirty years, until the generic revision of *Tatia* by Sarmento-Soares, Martins-Pinheiro (2008). Although kept as *incertae sedis* in Centromochlinae (Sarmento-Soares, Martins-Pinheiro, 2008: Tab. 1), *Tatia simplex* appears as a valid *Tatia* species in recent contribution (Calegari *et al.*, 2019).

In this study, a new species of *Tatia* from the upper rio Tocantins is described and the identity and geographic distribution of *T. simplex* is revised.

MATERIAL AND METHODS

Osteological preparations were cleared and stained (CS) for cartilage and bone using the method of Taylor, Van Dyke (1985). Osteological data were obtained from radiographs for species poorly represented in ichthyological collections. Specimens examined as radiographs are noted as "Rx" in the Comparative Material section. Osteological nomenclature follows the Teleost Anatomy Ontology (Dahdul *et al.*, 2010), with exceptions based on Birindelli (2014). Orientation of dentations on pectoral-fin spine as in Vanscoy *et al.* (2015). Drawings of cleared and stained specimens were rendered by camera lucida. Photographs of structural details were taken using a digital camera coupled to a Leica stereomicroscope. Species comparisons in diagnosis were provided based on direct examination of specimens, all mentioned in comparative material section.

Counts and measurements were made on the left side of the specimens whenever possible. All measurements are expressed as percents of standard length (SL), except subunits of the head, which are expressed as percents of head length (HL). Straight-line measurements were taken with a digital dial caliper, to the nearest 0.1 mm. Measurements and counts follow Sarmento-Soares, Martins-Pinheiro (2008). Counts of fin rays and bony elements were obtained from alcohol preserved and CS specimens. Fin ray counts include anteriormost spine (capital Roman numeral) or unbranched ray (lower case Roman numeral) and all subsequent branched rays (Arabic numeral). Caudal-fin ray counts included all principal rays (*i.e.* all inner branched rays and the first unbranched ray of the dorsal and ventral lobes, also referred to as outer principal rays). Gill rakers of the anterolateral row were counted on the first branchial arch (ceratobranchial+epibranchial). Branchiostegal rays and procurent caudal-fin rays were taken from cleared and stained specimens. Vertebral counts include the five elements incorporated into the Weberian complex plus one terminal element associated with the hypural complex (following Vari, Ferraris, 2013). Vertebral counts were taken from cleared and stained specimens or radiographs. Standard length (SL) is expressed in mm and all other measurements are expressed as percentage of the SL, except subunits of the head, which are expressed as percentage of the head length.

Institutional abbreviations follows Sabaj Pérez (2010), with the exception of: Instituto Nacional da Mata Atlântica [formely Museu de Biologia Professor Mello Leitão], Santa Teresa (MBML); Coleção Ictiológica do Núcleo de Pesquisas em Limnologia, Ictiologia e Aquicultura, Universidade Estadual de Maringá, Maringá (NUP); Ichthyological collection, Universidade Federal do Oeste do Pará, Santarém (UFOPA-I). In the list of comparative material examined, the museum abbreviation and catalog number are followed by the total number of specimens in that lot, range of standard length, cleared and stained (CS) or radiograph (Rx), and abbreviated collection data.

RESULTS

Tatia akroa, new species

urn:lsid:zoobank.org:act:4ECA989 8-25FD-417D-90F8-4C757A37C2A0

(Fig. 1, Tab. 1)

Holotype. UFOPA-I 671, 38.4 mm SL, Brazil, Tocantins State, rio Tocantins basin, rio Perdida, 9°11'23.44"S 47°15'59.14"W, 30 May 2013, L. Brito.

Paratypes. MZUSP 82349, 14, 2 CS, 27.3–35.4 mm SL, rio Palma, near village of Taipas, on road Dianópolis-Conceição do Tocantins, Dianópolis, 23 Nov 2002, C. R. Moreira, J. C. Nolasco. UFOPA-I 670, 1, CS, 34.26 mm SL, collected with the holotype.

Diagnosis: *Tatia akroa* differs from its congeners, except *T. britskii*, by the absence of adipose fin (*vs.* present). Differs from *T. britskii* by the caudal peduncle length (24.1–30.5% SL, mean 25.3 *vs.* 20.0–22.7%, mean 20.9); caudal peduncle depth (10.9–16.8% SL, mean 14.1 *vs.* 9.4–10.5%, mean 9.8); mesethmoid broad in the new species, smallest width approximately equal to its length, whereas slender in *T. britskii* (smallest width approximately three times length see Sarmento-Soares, Birindelli, 2014: fig. 2). Further differs from *T. simplex* by the posterior margin of dorsal-fin spine smooth (*vs.* with 1 to 3 distal denticulations). Further differs from *Tatia aulopygia* Kner, 1857, *Tatia brunnea* Mees, 1974, *T. caxiuanensis* Sarmento-Soares, Martins-Pinheiro, 2008, *Tatia dunni* (Fowler, 1945), *Tatia galaxias* Mees, 1974, *Tatia gyrina* (Eigenmann, Allen, 1942), *Tatia jaracatia* Pavanelli, Bifi, 2009, *Tatia intermedia*, *T. meesi* Sarmento-Soares, Martins Pinheiro, 2008, *T. neivai* (Ihering, 1930), and *Tatia strigata* Soares-Porto, 1995 by the cranial roof with two nuchal plates (*vs.* cranial roof with three nuchal plates, anterior one smallest, somewhat rounded) and by dotted color pattern on sides of body (*vs.* color pattern spotted or reticulated on flanks). Additionally distinct from *Tatia bockmanni* (Sarmento-Soares, Buckup, 2005), *Tatia concolor* Mees, 1974, *Tatia marthae* Vari, Ferraris, 2013, *Tatia punctata* Mees, 1974 by coracoid process somewhat large, about same length as pectoral-fin base (*vs.* coracoid process small, comparatively shorter than pectoral fin base). Further differs from *Tatia boemia* Koch, Reis, 1996, *Tatia caudosignata* DoNascimento, Albornoz-Garzón, García-Melo, 2019, and *T. nigra* Sarmento-Soares, Martins-Pinheiro, 2008, by the number of post-Weberian vertebrae, 30 (*vs.* between 32 to 36 vertebrae). From *Tatia reticulata* Mees, 1974, by posterior margin of dorsal spine with small denticulations, less than half in the width of spine axis (*vs.* well-formed retrorse denticulations, about same width as spine axis). From *Tatia melanoleuca* Vari, Calegari, 2014, *Tatia musaica* Royero, 1992, *Tatia orca* (Sarmento-Soares, Lazzarotto, Rapp Py-Daniel, Leitão, 2017), by small number of posterior denticulations, 11–15 (*vs.* large number of posterior denticulations on pectoral-spine, more than 20).

Description. Morphometric data presented in Tab. 1. Small size, examined adult specimens 38.3–49.3 mm SL. Body short, head slightly depressed anteriorly, progressively more elevated posteriorly. In dorsal view, profile of head longer than

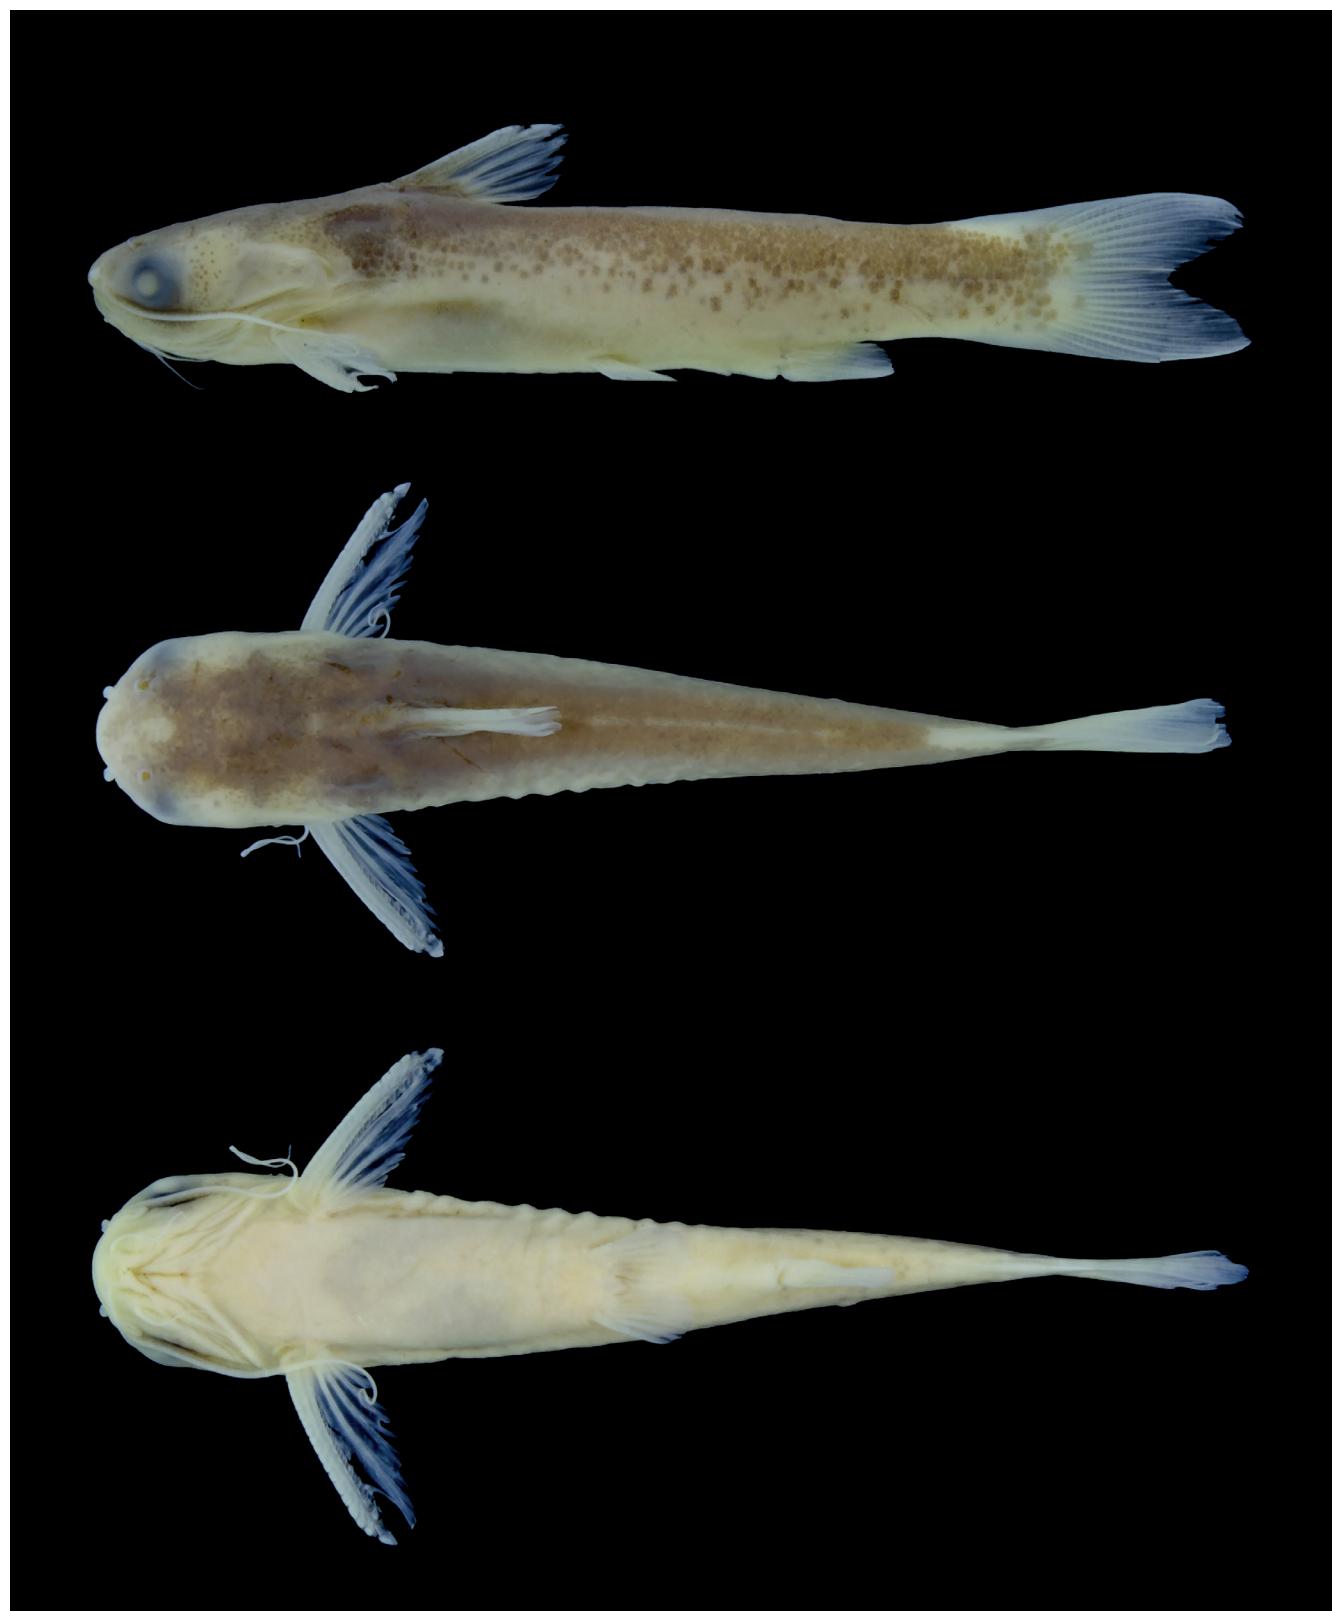

FIGURE 1 | *Tatia akroa*, lateral, dorsal and ventral views. UFOPA-I 671, holotype, male, 38.8 mm SL, rio Perdida, tributary of rio Sono, rio Tocantins basin, Tocantins State, Brazil.

TABLE 1 | Morphometric data of holotype and 16 paratypes of *Tatia akroa*. Holotype included in the ranges and means. SD = Standard Deviation.

	Holotype	Range	Mean	SD
Standard length (mm)	33.2	27.2–35.5	31.2	-

Mouth width	37.4	37.4–50.5	42.6	3.0

broad slightly convex from snout tip to pectoral-fin insertion. In lateral view, dorsal profile of body from dorsal-fin base to caudal fin slightly to distinctly convex. Ventral profile of head and abdomen almost straight. Greatest body width at pectoral-fin origin. Ventral profile of body gently concave between anal-fin base and caudal-fin

origin. Greatest body depth at origin of dorsal fin. Trunk from dorsal-fin base to caudal peduncle gradually compressed. Head integument thick, obscuring bones of cranial roof; adipose eyelid weakly developed; eye lateral on anterior portion of head; mouth terminal, upper lip extended posterolaterally, fleshy rictal fold well developed; snout margin rounded in dorsal view; anterior nostril tubular, located on anterior border of snout; posterior nostril somewhat larger, rounded, limited anteriorly by small skin flap; transverse distance between anterior nostrils slightly smaller than distance between posterior ones. Maxillary barbel elongate, reaching approximately vertical through middle of dorsal-fin or beyond; adpressed maxillary barbel fits in groove on the lateral portion of head, immediately above rictal fold and below eye; mental barbels very short, tips not reaching pectoral-fin base; bases of barbels arranged in arc along ventral surface of jaw; inner mental barbel about two-thirds length of outer mental (63.5–67.7% in outer mental). Posterior process of cleithrum moderately large, almost reaching vertical through base of dorsal-fin spine. Coracoid process developed, about same length as pectoral-fin base.

Dorsal fin II,5; originated slightly posterior to vertical through origin of pectoral fin; spinelet rigid, triangular in frontal view, covered by thin layer of skin; dorsal-fin spine straight, strong, pungent, shorter than first branched ray, with filamentous tip; anterior margin of dorsal-fin spine with 9–15 denticulations, posterior margin smooth ($n = 6$); first branched ray longest, subsequent rays decreasing gradually in length; last dorsal-fin ray approximately half length of first branched ray; distal margin of dorsal fin rounded. Adipose fin absent. Pectoral fin I,5; pectoral spine, rigid, pungent, anterior margin with 15–19 denticulations, posterior margin with 11–15 denticulations ($n = 6$); pectoral-fin spine denticulations becoming progressively more prominent distally; first branched ray longest, subsequent rays decreasing in length; posterior margin of pectoral fin obliquely truncate. Pelvic fin i,5; origin at or slightly posterior to middle of body; first branched ray longest, subsequent rays decreasing in length; posterior pelvic-fin margin straight or slightly rounded. Anal fin ii-iii,6 ($n=4$) or ii-iii, 7 ($n=13$); origin approximately on last third of standard length, posterior to vertical through tips of pelvic-fn rays; last ray unbranched, first and second branched rays longest; distal margin rounded. Caudal fin i,15;i; deeply forked, with approximately rounded lobes; dorsal and ventral caudal-fin lobes equal in length; outer principal rays unbranched, seven branched rays on dorsal lobe and eight branched rays on ventral lobe; 14–17 upper procurrent, 13–15 lower procurrent rays ($n = 3$).

Rostral border of cranium with mesethmoid longer than broad; premaxilla with synchondral articulation; cranial fontanel narrow and elliptical, enclosed by mesethmoid and frontals (Fig. 2). Nasal ossified as short tubular bone situated between mesethmoid cornua and lateral ethmoid, not sutured to mesethmoid. Lateral ethmoid not participating in dorsal face of cephalic shield. Autopalatine rod-like, oriented almost parallel to longitudinal axis of body; maxilla slightly elongated, about twice the size of autopalatine; vomer arrow-shaped with short rostral-lateral processes. Jaws of equal size; premaxilla and dentary slender, each with two or three rows of robust conical teeth. Anterior nuchal plate absent; middle nuchal plate slightly concave along lateral margins; posterior nuchal plate short, projected laterally, with prominent tip. Epioccipital process very small (Fig. 2).

Hyomandibula broad, projected anteriorly, connected to both quadrate and

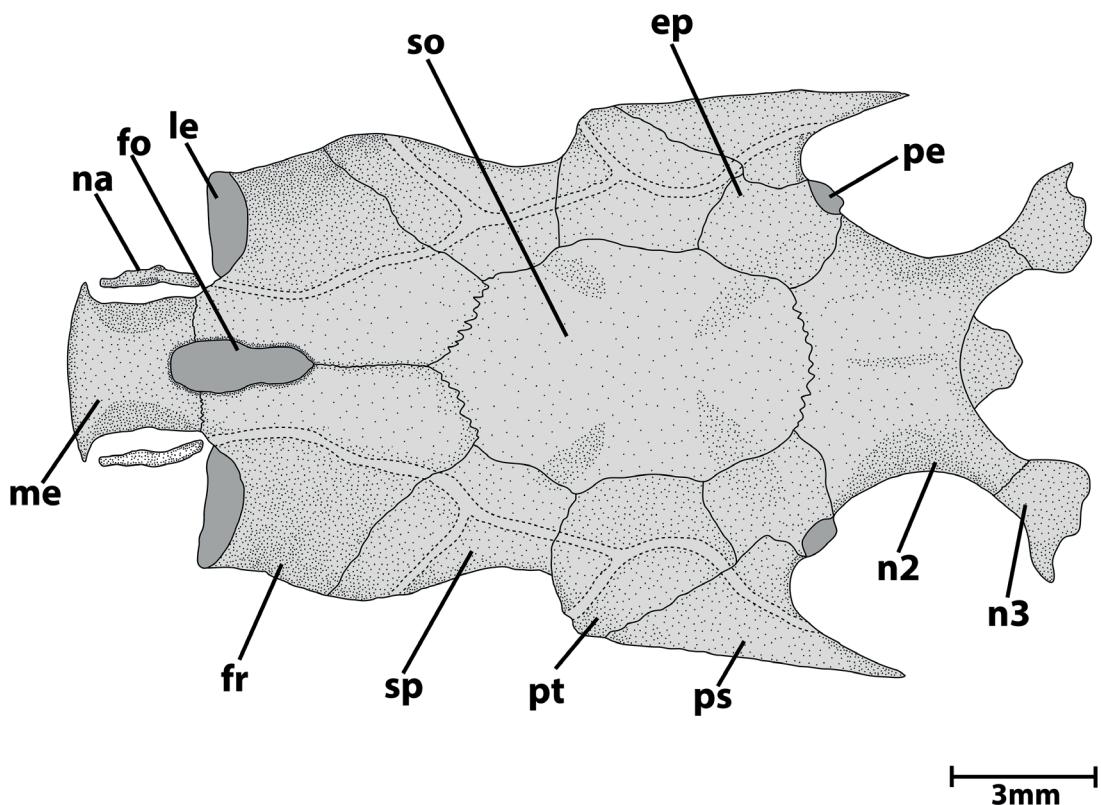

FIGURE 2 | Neurocranium of *Tatia akroa*, UFOPA-I 670, 34.3 mm SL. Dorsal view. Abbreviations: **ep**, epioccipital; **fo**, cranial fontanel; **fr**, frontal; **le**, lateral ethmoid; **me**, mesethmoid; **na**, nasal; **n2**, second nuchal plate; **n3**, third nuchal plate; **pe**, pterotic; **ps**, posttemporal-supracleitrum; **pt**, pterotic; **so**, supraoccipital; **sp**, sphenotic. Scale bar = 3 mm.

metapterygoid through cartilage and deeply dentate suture. Metapterygoid as a wide lamina, joined to quadrate via suture (Fig. 3). Quadrate trapezoidal, with broad base, sutured to preopercle, hyomandibula and metapterygoid; long preopercle ventral margins sutured to both quadrate and hyomandibula; suprapreopercle present as long canal bone; preopercular canal exiting on anterior portion of pterotic. Opercle laminate, ornamented, and broadly subtriangular.

Hyoid arch with compact parurohyal with short ventral process; short dorsal hypohyal associated with comparatively large ventral hypohyal; anterior ceratohyal well developed, posterior ceratohyal smaller than others one; branchiostegal ray articulated to hyoid arch; six branchiostegal rays, four slender rays associated with anterior ceratohyal, two flattened rays with posterior ceratohyal (Fig. 4). Branchiostegal membrane broadly united to isthmus.

Branchial arches with urohyal close to basibranchial 2; basibranchial 2 cartilaginous, broadest anteriorly, usually separated by gap from basibranchial 3; basibranchial 3 shorter, forming osseous rod; basibranchial 4 large, flattened and cartilaginous; basibranchial 2 bordered laterally by cartilaginous head of hypobranchial 1; basibranchial 3 between cartilaginous head of hypobranchial 2 and cartilaginous hypobranchial 3; basibranchial

Abbreviations: **ach**, anterior ceratohyal; **bra**, branchiostegal rays; **dhy**, dorsal hypohyal; **ihy**, interhyal; **pch**, posterior ceratohyal; **vhy**, ventral hypohyal; **uhy**, urohyal. Scale bar = 1 mm.

4 bordered laterally by cartilaginous head of ceratobranchial 4 and caudally by cartilaginous head of ceratobranchial 5.

Hypobranchials 1 and 2 subtriangular, mostly osseous, elongate and expanded

laterally, with cartilaginous tips; hypobranchial 3 completely cartilaginous, trapezoidal; hypobranchial 4 absent. Five ceratobranchials, mostly ossified, with cartilage on both ends. Ceratobranchials supporting single row of rakers; fifth ceratobranchial expanded postero-medially to support lower pharyngeal toothplate with short conical teeth. Four epibranchials, all largely ossified except for cartilaginous ends, supporting few rakers each, close to articulation with ceratobranchials. Epibranchials 1 and 2 rod-like; epibranchial 3 with posterior uncinate process in articulation to epibranchial 4; epibranchial 4 with laminar extension; reduced accessory cartilage, located on angle between cartilaginous ends of epibranchial 4 and ceratobranchial 4. Pharyngobranchial 1 absent; pharyngobranchial 2 short, cartilaginous, somewhat ellipsoid, placed between anteromedial cartilaginous tips of epibranchials 1 and 2; pharyngobranchial 3 elongate, ossified, with expanded posterior border; pharyngobranchial 4 ossified. Upper pharyngeal tooth plate bearing conical teeth, supported by pharyngobranchial 3 and 4, and also epibranchials 3 and 4.

Infraorbital 1 with ventro-lateral process restricted to anterior border of eye, and followed by four canal-like bones, in incomplete infraorbital series. Lateral line on body straight, inconspicuous, with ossified canal bones only anteriorly, unbranched at caudal fin.

Ribs 8–9 attached to consecutive vertebrae 6–13, becoming progressively smaller posteriorly. Total vertebrae 35 (N= 4), observed in cleared and stained (CS) and radiographed specimens (R).

Color in alcohol. Color light brown with dots, formed by chromatophores scattered on the head and mid-dorsal portions of body; sometimes dorsal surface of head and dorsolateral region darker along entire trunk, with more concentrated chromatophores from mid-dorsal region to lateral line. Sides of body with light brown chromatophores, becoming sparse ventrally. Fins almost hyaline; rays mottled with pale brown spots along base. Dorsal fin with a dark spot localized in proximal region. Caudal-fin base with irregular black to brown spots; fin becoming hyaline towards distal margin.

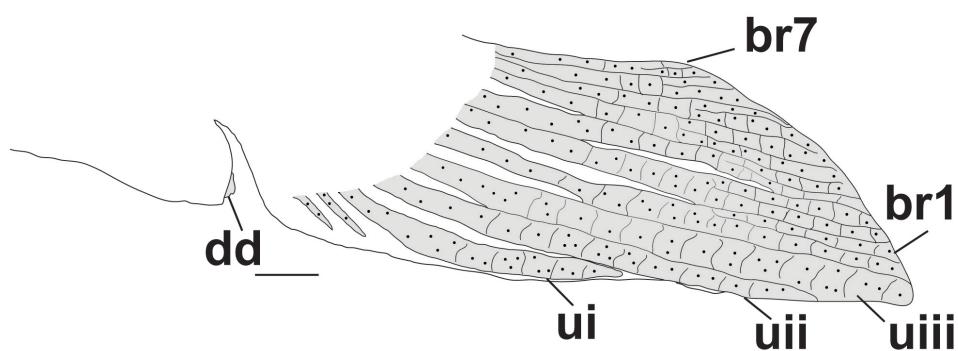

FIGURE 5 | Anal fin of *Tatia akroa*. UFOPA-I 671, male, 38.8 mm SL, holotype. Abbreviations: **br1**, branched ray one; **br7**, branched ray seven; **dd**, defferent duct; **ui**, unbranched first ray; **uii**, unbranched second ray; **uiii**, unbranched third ray. Scale bar = 1 mm.

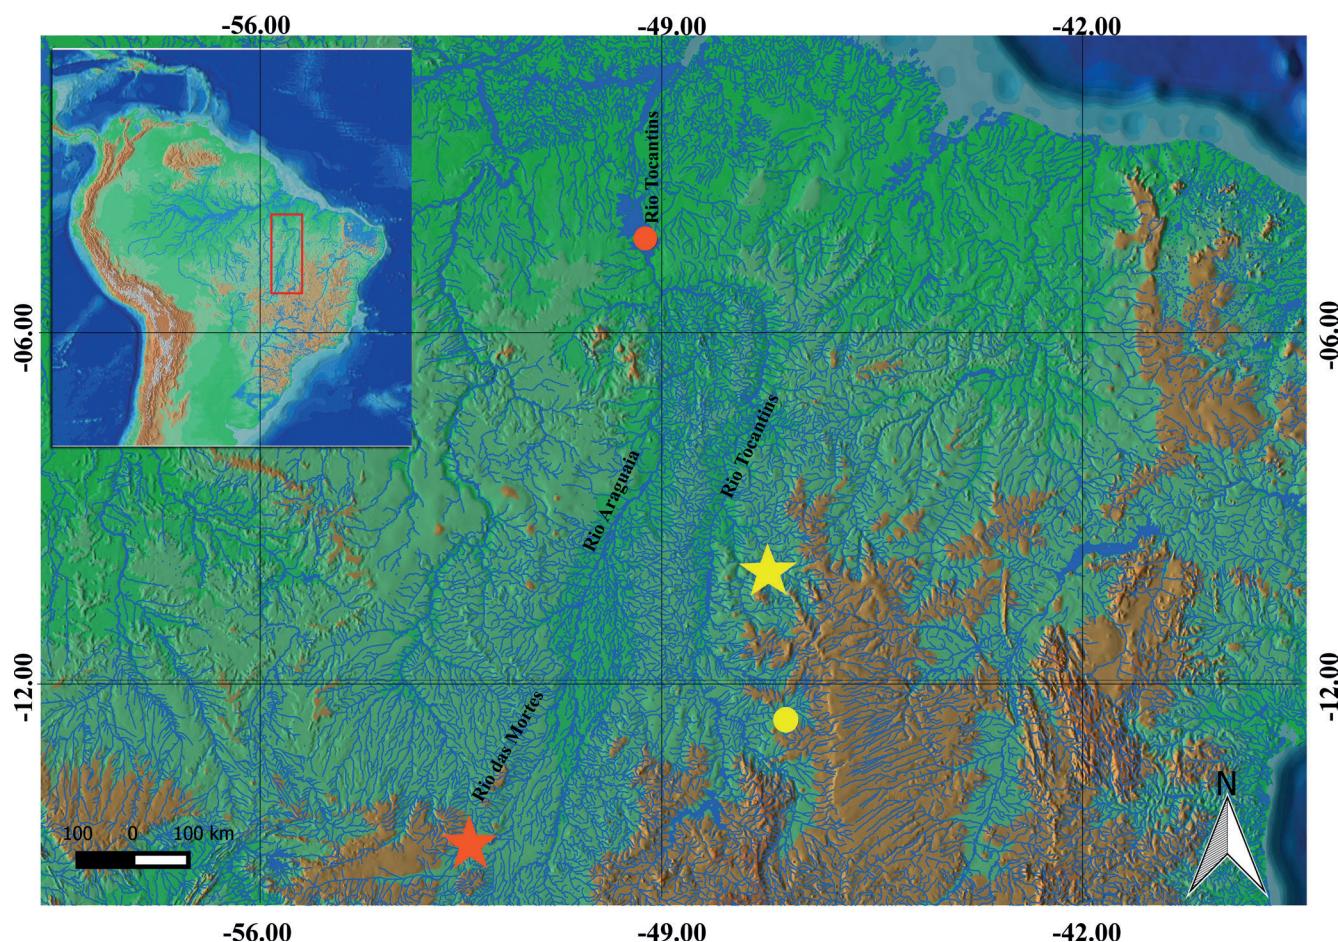

FIGURE 6 | Distribution of *Tatia akroa* (yellow) and *T. simplex* (orange). Stars represent type localities.

Sexual dimorphism. Observed in one male with partially modified anal fin for insemination (Figs. 1, 5). Five first proximal radials closely together, not fused, with sutures visible. Last three proximal radials elements arranged as in non-breeding and females (according previous descriptions for congeners). Unbranched and first branched anal-fin rays fused together to form a structure for insemination at anterior portion of the anal fin. Urogenital opening at base of anal fin as simple pore at the distal tip of a tubular structure bound by integument. Diferent duct externally visible as a genital papilla.

Distribution. *Tatia akroa* is known from the upper portion of the rio Tocantins drainage (Fig. 6).

Ecological notes. One of the specimens examined was dissected and its stomach contained fragments of terrestrial insects including Diptera and Coleoptera.

Conservation status. *Tatia akroa* is known from the rio Perdida and rio Palma, upper rio Tocantins drainage. Considering its Extent of Occurrence (EOO) and that no major

threats to the species were detected in the area of distribution we suggest that *T. akroa* should be categorized as least concern (LC) according to the International Union for Conservation of Nature categories and criteria (IUCN, 2019).

Etymology. The specific name is a reference to the Akroá indigenous people, inhabitants of lands from eastern Tocantins to southern Piauí until the XIX century (Apolinário, 2005). The Akroá lived along valleys on Serra Geral do Tocantins, a watershed divide between the right margin of rio Tocantins and rio Parnaíba upper valleys respectively. Their territory included the rio Manuel Alves sub-basin of rio Tocantins, distribution range of the new *Tatia* species. A noun in apposition.

DISCUSSION

The parieto-supraoccipital joined to middle nuchal plate, with resultant absence of an anterior nuchal plate, is a condition shared by *Tatia akroa* and ten species presently assigned under *Tatia*, namely: *T. bockmanni*, *T. britskii*, *T. concolor*, *T. marthae*, *T. melanoleuca*, *T. musaica*, *T. orca*, *T. punctata*, *T. reticulata*, and *T. simplex*. In addition, the lack of anterior nuchal plate is shared by a few Centromochlinae species (*Balroglanis carolae*, *B. macracanthus*, *B. schultzi*, *Duringlanis romani*, *Ferrarissoaresia ferrarisi*, and *F. meridionalis*) and by all *Gelanoglanis* species (*G. stroudi*, *G. nanonocticolus*, *G. travieso*, and *G. pan*). Among the species of *Tatia* a parieto-supraoccipital joined to anterior nuchal plate is shared by *Tatia aulopygia*, *T. boemia*, *T. brunnea*, *T. caudosignata*, *T. caxiuanensis*, *T. caudosignata*, *T. dunnii*, *T. galaxias*, *T. gyrina*, *T. jaracatia*, *T. intermedia*, *T. meesi*, *T. neivai*, *T. nigra*, and *T. strigata*.

Among the centromochlins lacking an anterior nuchal plate, a restricted group of *Tatia* species composed by *Tatia akroa*, *T. bockmanni*, *T. britskii*, *T. concolor*, *T. marthae*, *T. punctata*, and *T. simplex* are morphologically very similar. Besides the arrangement of cranial nuchal plates, a modified anal fin of mature males with reduced posterior rays, bearing one or two (sixth and/or seventh branched rays) smaller or rudimentary; and also a similar color pattern, with scattered dots over a pale body and translucent fins, with the exception of *T. punctata*, which specimens exhibits a vermiculated color pattern. Most of these species were originally described in *Tatia*, however remained for a long time under *Centromochlus* (i.e. *Tatia concolor*, *T. simplex*, and *T. punctata*), or *Glanidium* (*Tatia bockmanni*), and some (i.e. *Tatia britskii*) were originally described under *Centromochlus*, and now placed under *Tatia* (Calegari et al., 2019). The difficulties in solving relationships of some of these species within *Tatia* are that only type material is available, with few specimens in collections. The few specimens available in fish collections make accurate identification of these species difficult, and some names as *Tatia simplex* and also *T. marthae*, were based upon juveniles specimens only.

Tatia simplex was described as having an extremely small adipose fin, smaller than other centromochlins species (Mees, 1974: 93). Although the significance of reduced adipose fin in the holotype was stated as uncertain regarding the diagnosis of the species, additional specimens with a reduced adipose fin were found in rio Tocantins drainage. Analysis of these specimens support the hypothesis that *T. simplex* is distinguished from all Centromochlinae by the adipose-fin base length corresponding to 1.5% or less

in SL (*vs.* adipose-fin base length more than 2% in SL, even in species with adipose fin proportionally smaller, as *Centromochlus existimatus* and *C. heckelii*). *Tatia simplex* is further distinguished from *C. existimatus* and *C. heckelii* by lacking anterior nuchal plate (*vs.* anterior nuchal plate present) and shorter pectoral-fin spine (20.7–22.7% of SL *vs.* 29.3–41.6% of SL). *Tatia simplex* differs from *T. akroa* and *T. britskii*, the only species lacking an adipose fin, by the posterior border of dorsal-fin spine with 1 to 3 distal denticulations (*vs.* smooth margin). Among species of Centromochlinae that share the absence of anterior nuchal plate (*i.e.* *Balroglanis macracanthus*, *B. schultzi*, *Duringlanis romani*, *Ferrarisoaresia meridionalis*, *T. bockmanni*, *T. concolor*, *T. punctata*, *T. reticulata*, and *T. simplex*), *Tatia simplex* differs from both *Balroglanis macracanthus* and *B. schultzi* by having posterior margin of dorsal-fin spine smooth (*vs.* denticulated); differs from *T. punctata* and *T. concolor* by irregular or retrorse orientation of dentations along anterior margin of pectoral-fin spine (*vs.* regularly spaced antorse dentations); and by the morphology of male modified anal fin, specifically, the last branched anal-fin ray progressively shorter than anterior most (*vs.* last ray abruptly reduced, size half that of preceding one and visible only through dissection).

Tatia simplex was originally described from rio das Mortes, tributary of left margin of rio Araguaia, on Mato Grosso State, Brazil. This species is scarcely represented in scientific collections. The revision of distribution patterns based on additional material of *T. simplex* suggests that the species is restricted to the Tocantins-Araguaia system, with records from rio das Mortes and lower rio Tocantins (Fig. 7).

Comparative material examined. *Ferrarisoaresia meridionalis*. **Brazil.** Mato Grosso State. ACKNOWLEDGMENTS

We thank Lúcia R. Py-Daniel (INPA), Aléssio Datovo, Osvaldo Oyakawa and Michel Gianeti (MZUSP), Carlos do Nascimento (IAvH-P) and Paulo Lucinda (UNT) for curatorial assistance. We are indebted to C.J. Ferraris and J.L.O. Birindelli (MZUEL), for further comments and suggestions on manuscript draft. JSS thanks the Fundação Amazônia de Amparo a Estudos e Pesquisa (FAPESPA) for the fellowship granted (ICAAF #056/2016). ALCC and FRVR were partly supported by CNPq (ICAAF #436763/2018-4) and Programa de Fortalecimento dos Grupos de Pesquisa/UFOPA. We are indebted to Instituto Nossos Riachos (INR) database for images of some specimens in present study.
