Abstract. We propose a discrete approximation scheme to a class of Linear Quadratic Continuous Time Problems. It is shown, under positiveness of the matrix in the integral cost, that optimal solutions of the discrete problems provide a sequence of bounded variation functions which converges almost everywhere to the unique optimal solution. Furthermore, the method of discretization allows us to derive a number of interesting results based on finite dimensional optimization theory, namely, Karush-Kuhn-Tucker conditions of optimality and weak and strong duality. A number of examples are provided to illustrate the theory.

Mathematical subject classification: 49M25, 49N10, 90C20.

Key words: Linear Quadratic problems, Continuous time optimization, discrete approximation, strict convexity.

1 Introduction

We propose a discretization scheme to compute approximate solutions of linear-quadratic continuous time problems (LQCTP) of the form

$$\text{Minimize} \quad \int_0^T \left[(1/2)x'(t)Q(t)x(t) + a'(t)x(t) \right] dt$$

$$\text{Subject to} \quad B(t)x(t) - \int_0^t K(t,s)x(s)\,ds - c(t) \leq 0$$

$$x(t) \geq 0.$$

The matrix Q associated with the integral cost consists of time-varying continuous functions as entries and the rest of the parameters of the problem a, c, B and K are functions of bounded variation; $x(t)$ is the decision variable.

The method of discretization consists of taking a sequence of partitions of the interval $[0, T]$ in equidistant intervals such that in each interval of a particular partition we apply the trapezoidal rule in the cost and in the constraints of the original problem. For each discretization we get a finite dimensional quadratic programming problem. We are able to prove that any sequence of continuous solutions obtained from the optimal solutions of the discretized problems converges almost everywhere to the optimal solution of the original continuous time problem. We point out that this convergence is independent of particular integration rule adopted. What may differ is the order of convergence which will be discussed elsewhere.

We illustrate the power of our discretization method to approximately solve linear-quadratic continuous time problems with a series of examples. In these examples we are capable of actually finding analytical solutions, where the discrete optimal solutions play a major role in showing how the solutions should look like. The confirmation of optimality is made by using the Karush-Kuhn-Tucker conditions of optimality provided in Section 6.

The method of solving (LQCTP) presented here is an extension of the purely linear cases studied by Buie and Abrham [3] and Pullan [10] to linear-quadratic problems.

The theoretical approach to prove convergence of a subsequence of continuous approximate solutions to an optimal solution of the LQCTP enables us to also derive some duality results for LQCTP. The finite dimensional pair of problems obtained in our discretization scheme are convex and concave, respectively. Then, there is no duality gap between them [4]. Due to weak duality, Theorem 5.1 below, the value of the maximization problem (D) is at most equal to the value of the minimization problem (LQCTP). We show that the gap closes up when we refine the partition of $[0, T]$. In the limit we have optimality (strong duality).

As it is well known, finite dimensional quadratic problems have duals with only dual variables. This is made possible via primal variable elimination of the dual.

A direct approach of eliminating the primal variables of the dual in a continuous time version is now more complicated. However, due to the approximation scheme and duality relationships between the finite dimensional problems, we can, as explained above, provide a duality theory for the linear-quadratic problem.

A duality theory for purely linear continuous time problems was first investigated in [11]. After that, duality theory has been extended in a number of directions, see, for instance, [12, 5, 6, 1, 2]. Pullan [10] considers a special class of linear problems, called separated continuous linear programs, proposes a discretization method to solve problems in this class and derives a strong duality result. Philpot [9] considers a linear continuous time problem modelling shortest path problems in graphs, where edge distances can vary with time. Under some regularity on the edge distances he also establishes strong duality.

It seems that continuous time problems with quadratic integral cost and linear (integral) operator in the constraints in the present form of this paper has not been considered elsewhere in the literature.

We now fix the notation used in this paper. The space of matrices with k rows and l columns is denoted by $\mathbb{R}^{k \times l}$. We will use the following definitions for norm of vectors, matrices and variation of the functions. Let $x = (x_1, \cdots, x_k)'$ be a vector, $A = (a_{ij})$ be a matrix and

$$||x|| = \sum_{i=1}^{k} |x_i| \quad \text{and} \quad ||A|| = \sum_{i=1}^{k} \sum_{j=1}^{l} |a_{ij}|$$

denote the norms of x and A, respectively. Let $\text{abs}(x)$ mean $(|x_1|, \ldots, |x_2|)$. Let $f : [0, T] \to \mathbb{R}$ be a given function. The number

$$V[0, T, f(t)] = \sup_{0 = t_0 < \cdots < t_n = T} \sum_{i=0}^{n} |f(t_i) - f(t_{i-1})|$$

finite or infinite is called the variation of the function f on the interval $[0, T]$. We say that f is a function of bounded variation on $[0, T]$, if $V[0, T, f(t)] < +\infty$. Matrix functions $A(\cdot) : [0, T] \to \mathbb{R}^{k \times l}$ are of bounded variation if each entry of the matrix is a function of bounded variation. We denote the space of matrix functions of bounded variation by $BV([0, T]; \mathbb{R}^{k \times l})$.

We finish this section by summarizing the organization of the paper. Section 2 is devoted to recalling the LQCTP and introducing its discretization. In Section 3

the dual problem and its discretization are introduced. Some facts about duality for finite dimensional quadratic problems are gathered in Proposition 3.1 below. The standing hypothesis and results of convergence are the subject of Section 4. Results of duality are presented in Section 5 and the Karush-Kuhn-Tucker conditions of optimality in Section 6. Numerical examples are discussed Section 7. Finally, in Section 8, some comments and final considerations are made.

2   The linear-quadratic problem and its discretization

We start recalling the LQCTP from the introduction.

$$\text{Minimize} \quad \int_0^T \left[(1/2)x'(t)Q(t)x(t) + a'(t)x(t) \right] dt$$

$$\text{Subject to} \quad B(t)x(t) - \int_0^t K(t,s)x(s)\,ds - c(t) \leq 0 \qquad (1)$$

$$x(t) \geq 0.$$

Here $a(t) : [0,T] \to \mathbb{R}^N$, $B(t) : [0,T] \to \mathbb{R}^{m \times N}$ and $c(t) : [0,T] \to \mathbb{R}^m$ are functions of bounded variation which are supposed to be continuous on the right on the interval $[0,T)$ and $Q : [0,T] \to \mathbb{R}^{N \times N}$ is a continuous function. $K : [0,T] \times [0,T] \to \mathbb{R}^{m \times N}$ is a constant matrix and $x(\cdot) : [0,T] \to \mathbb{R}^N$ is a choice variable. Precise assumptions will be made clear in Section 4. We point out that right continuous bounded variation functions can jump on right endpoint T of the interval $[0,T]$, but cannot jump at the left point of it.

We now introduce the discretization for LQCTP. Let $\pi_n := \{t_i^n\}$ be a partition of the interval $[0,T]$ in l_n sub-intervals, in which $t_i^n := i(T/l_n)$, for $i = 1, 2, \ldots, l_n$. Let $A : [0,T] \to \mathbb{R}^{k \times l}$ and $\alpha : [0,T] \to \mathbb{R}^k$ be given functions, which are matrix valued and vector valued, respectively. We use the notation $A_i^n := A(t_i^n)$ and $\alpha_{ni} := \alpha(t_i^n)$ for $i = 1, 2, \ldots, l_n$ unless stated differently. The resulting discrete quadratic problem is given by

$$\text{Minimize} \quad (T/l_n)\left[(1/2)x_n'Q_nx_n + a_n'x_n \right]$$

$$\text{Subject to} \quad G_nx_n \leq c_n,$$

$$x_n \geq 0,$$

where

$$a'_n = (a'_{n0} : a'_{n1} : \cdots : a'_{nl_n}) \text{ with } a_{n0} = (1/2)a(0), a_{nl_n} = (1/2)a(T),$$

$$a_{ni} = a(t_i^n) \text{ for } i = 1, 2, \cdots, l_n - 1,$$

$$c'_n = (c'_{n0} : c'_{n1} : \cdots : c'_{nl_n}) \text{ with } c_{n0} = (1/2)c(0), c_{nl_n} = (1/2)c(T),$$

$$c_{ni} = c(t_i^n) \text{ for } i = 1, 2, \cdots, l_n - 1,$$

$$Q_n = \begin{pmatrix} \frac{1}{2}Q_0^n & 0 & 0 & \cdots & & 0 \\ 0 & Q_1^n & 0 & \cdots & & 0 \\ \vdots & & \ddots & & & \vdots \\ 0 & \cdots & 0 & Q_{l_n-1}^n & & 0 \\ 0 & \cdots & 0 & 0 & & \frac{1}{2}Q_{l_n}^n \end{pmatrix}$$

and

$$G_n = \begin{pmatrix} \frac{1}{2}B_0^n & 0 & 0 & 0 & \cdots & & 0 \\ 0 & B_1^n & 0 & 0 & \cdots & & 0 \\ 0 & 0 & B_2^n & 0 & \cdots & & 0 \\ \vdots & & & \ddots & & & \vdots \\ 0 & 0 & \cdots & 0 & B_{l_n-1}^n & & 0 \\ 0 & 0 & \cdots & 0 & 0 & & \frac{1}{2}B_{l_n}^n \end{pmatrix} - \frac{T}{l_n} \begin{pmatrix} \frac{1}{4}K & 0 & 0 & 0 & \cdots & & 0 \\ \frac{1}{2}K & \frac{1}{2}K & 0 & 0 & \cdots & & 0 \\ \frac{1}{2}K & K & \frac{1}{2}K & 0 & \cdots & & 0 \\ \vdots & & & & \ddots & & \vdots \\ \frac{1}{2}K & K & \cdots & K & \frac{1}{2}K & & 0 \\ \frac{1}{4}K & \frac{1}{2}K & \cdots & \frac{1}{2}K & \frac{1}{2}K & & \frac{1}{4}K \end{pmatrix}$$

where $Q_0^n = Q(0)$, $Q_{l_n}^n = Q(T)$ and $Q_i^n = Q(t_i^n), i = 1, 2, \cdots, l_n - 1$; $B_0^n = B(0)$, $B_{l_n}^n = B(T)$ and $B_i^n = B(t_i^n)$, $i = 1, 2, \cdots, l_n - 1$.

3 The dual problem, its discretization and basic results

The dual of (LQCTP) is defined by

$$\text{Maximize } \int_0^T \Bigg[-(1/2)w'(t)G(t)Q^{-1}(t)G'(t)w(t) - c'(t)w(t)$$

$$-a'(t)Q^{-1}(t)G'(t)w(t) + \mu'(t)Q^{-1}(t)G'(t)w(t)$$

$$+\mu'(t)Q^{-1}(t)a(t) - (1/2)\mu'(t)Q^{-1}(t)\mu(t)$$

$$-(1/2)a'(t)Q^{-1}(t)a(t) \Bigg] dt$$

$$\text{Subject to } w(t) \geq 0 \quad \text{and} \quad \mu(t) \geq 0,$$

where $G'(t)x(t) := B'(t)x(t) - \int_t^T K(s,t)x(s)ds$ and $G(t)x(t) := B(t)x(t) - \int_t^T K(t,s)x(s)ds$. Here the dual variables w, $\mu : [0,T] \to I\!\!R^n$ are functions of bounded variation. We now write the dual problem in a simplified form

$$\text{Maximize} \quad \int_0^T \left[-(1/2)\theta'(t)M(t)\theta(t) + N'(t)\theta(t) + R(t) \right] dt$$

$$\text{Subject to} \quad \theta(t) \geq 0$$

where,

$$M(t) = \begin{pmatrix} G(t)Q^{-1}(t)G'(t) & -G(t)Q^{-1}(t) \\ -Q^{-1}(t)G'(t) & Q^{-1}(t) \end{pmatrix},$$

$$N(t) = \begin{pmatrix} -c(t) - G(t)Q^{-1}(t)a(t) \\ Q^{-1}(t)a(t) \end{pmatrix},$$

$$R(t) = -(1/2)a'(t)Q^{-1}(t)a(t)\theta(t) = \begin{pmatrix} w(t) \\ \mu(t) \end{pmatrix}.$$

Analogously, we introduce the discretization of the dual problem

$$\text{Maximize} \quad (T/l_n)\left\{ -(1/2)w_n'G_nQ_n^{-1}G_n'w_n + w_n'(-c_n - G_nQ_n^{-1}a_n) \right.$$

$$\left. \mu_n'Q_n^{-1}G_n'w_n + \mu_n'Q_n^{-1}a_n - (1/2)\mu_n'Q_n^{-1}\mu - (1/2)a_n'Q_n^{-1}a_n \right\}$$

$$\text{Subject to} \quad w_n \geq 0 \quad \text{and} \quad \mu_n \geq 0.$$

Again, G_n, Q_n, c_n and a_n are the same as in the primal discrete problem, $\mu_n := (\mu(t_0^n) : \dots , \mu(t_{l_n}^n))$ and $w_n := (w(t_0^n) : \dots : w(t_{l_n}^n))$. The discrete dual can also be written in a simplified form

$$\text{Maximize} \quad -(1/2)\theta_n'M_n\theta_n + N_n'\theta_n + R_n$$

$$\text{Subject to} \quad \theta_n \geq 0,$$

where

$$M_n = \begin{pmatrix} G_nQ_n^{-1}G_n' & -G_nQ_n^{-1} \\ -Q_n^{-1}G_n' & Q_n^{-1} \end{pmatrix} \quad N_n = \begin{pmatrix} -c_n - G_nQ_n^{-1}a_n \\ Q_n^{-1}a_n \end{pmatrix},$$

$$R_n = -(1/2)a_n'Q_n^{-1}a_n \quad \theta_n = \begin{pmatrix} w_n \\ \mu_n \end{pmatrix}.$$

For a fixed n, the pair of finite dimensional problems (P_n) and (D_n) form the usual pair of primal-dual problems in the classical theory of optimization chapter for quadratic problems.

We state some basic facts related to this pair of primal-dual problems that will be needed in the sequel.

Proposition 3.1.   *See, for instance,* [8].

a.   *Let x_n and (w_n, μ_n) be (P_n) and (D_n) feasible, respectively. If the (primal) cost of x_n coincides with the (dual) cost of (w_n, μ_n), then x_n and (w_n, μ_n) are (P_n) and (D_n) optimal, respectively.*

b.   *Let x_n be (P_n) optimal. If there exists $(w_n, \mu_n) \geq 0$ such that*

   (a) $Q_n x_n + a'_n + w'_n(G_n x_n - c_n) - \mu_n = 0;$

   (b) $w'_n(G_n x_n - c_n) - \mu'_n x_n = 0,$

   then (w_n, μ_n) is (D_n) optimal. Conversely, if (w_n, μ_n) is (D_n) optimal then (a) and (b) are satisfied at (x_n, w_n, μ_n).

4   Hypothesis and convergence results

We now introduce some definitions and hypothesis which will be used throughout the remainder of this paper. Given $\alpha \in \mathbb{R}$, let

$$S_\alpha = \left\{ x \in BV([0, T]; \mathbb{R}^N) : x(\cdot) \text{ satisfies (1) and} \right.$$
$$\left. \int_0^T [(1/2)x'(t)Q(t)x(t) + a'(t)x(t)] \, dt \leq \alpha \right\}$$

and

$$W_\alpha = \left\{ \theta \in BV([0, T]; \mathbb{R}^{m+N}) : \theta \geq 0 \text{ and} \right.$$
$$\left. \int_0^T [-(1/2)\theta'(t)M(t)\theta(t) + N'(t)\theta(t) + R(t)] \, dt \leq \alpha \right\}$$

be the α-sub-level sets of the primal and dual problems, respectively.

We assume that

(H1) $a(t), c(t)$ and $B(t)$ are matrix functions of bounded variation, $Q(t)$ is a continuous positive definite matrix function and K is a constant matrix;

(H2)   For every positive integer n, there exist feasible solutions to problems (P_n) and (D_n);

(H3)   There exists $\alpha \geq 0$ such that $\int_0^T \left[(1/2)x'(t)Q(t)x(t) + a'(t)x(t)\right]dt \leq \alpha$, $\forall x$ satisfying (1).

We observe that (H1) implies that LQCTP is a convex programming problem whose cost is strictly convex. In that case the optimal solution is unique (apart from a zero-measure set). This observation has an important implication in the convergence of the approximate solutions since all subsequences will converge to the same unique optimal solution (a.e.). In fact, this procedure ensures the convergence of any sequence obtained via discretization to the optimal solution.

We can only guarantee that a perturbation of the discrete Primal quadratic problem, which takes into account the error generated by the rule of integration, is feasible. But, to keep the arguments of the proof easier to understand and also to parallel some results in reference [1], which is the basis of our work, we assume hypothesis (H2), without loss of generality. Actually our hypothesis (H2) corresponds to an algebraic condition imposed in [1] to ensure feasibility.

Note that in hypothesis (H1), except for $Q(\cdot)$ that is supposed to be continuos, all functions are of bounded variation. The continuity of $Q(\cdot)$ is essential to guarantee the boundedness of the sub-level sets of the cost functional of $LQCTP$. This boundedness is central in the convergence proof which, in turn, is based on compactness arguments over sub-level sets of the cost functional of the problem.

The proof of the expected boundedness is in Lemma 4.1; soon after Lemma 4.1, we show why the continuity of $Q(\cdot)$ cannot be relaxed. It will be clear in the proofs that if we assume the sets of feasible solutions of (LQCTP) and (D) are bounded we get convergence of a subsequence, even when $Q(\cdot)$ is of bounded variation. So, the continuity of $Q(\cdot)$ is a trade off to increase the generality of the method.

We say that π_{n+1} is a refinement of π_n if $\pi_n \subset \pi_{n+1}$. Hereafter, we consider only sequences of partitions $\{\pi_n\}$ in which π_{n+1} is a refinement of π_n.

We introduce some notation needed in the sequel. Given $\alpha \in \mathbb{R}$, let

$$S_{n,\alpha} = \left\{ x \in \mathbb{R}^n : G_n x \leq c_n, x \geq 0; (T/2l_n) x' Q_n x + b'_n x \leq \alpha \right\}.$$

Let x_n and θ_n be the primal and dual optimal solutions of the discrete problems, respectively. We define their *continuous extensions* $x_n(t)$ and $\theta_n(t)$ to the whole interval $[0, T]$, by

$$
\begin{aligned}
x_n(t) &:= [(t - t_i^n)/(l_n)](x_{n,i+1} - x_{n,i}) + x_{n,i} \quad \text{for} \quad t_i^n \leq t \leq t_{i+1}^n, \\
&\quad i = 0, 1 \cdots, l_n - 1;
\end{aligned}
\tag{2}
$$

$$
\begin{aligned}
\theta_n(t) &:= [(t - t_i^n)/(l_n)](\theta_{n,i+1} - \theta_{n,i}) + \theta_{n,i} \quad \text{for} \quad t_i^n \leq t \leq t_{i+1}^n, \\
&\quad i = 0, 1 \cdots, l_n - 1.
\end{aligned}
\tag{3}
$$

It is easy to verify that the extension $\theta_n(t)$ obtained from the discrete dual optimal solution is a dual feasible solution (not necessarily optimal). However, $x_n(t)$ is not necessarily primal feasible.

Our next step is to state and prove two technical lemmas needed for the main results of this section.

Lemma 4.1. *Let $\alpha \in \mathbb{R}$ be given. Suppose hypothesis* (H1)-(H3) *are valid. Then S_α is a bounded set. Furthermore, $S_{n\alpha}$ is uniformly bounded for $n \in \mathbb{N}$.*

Proof. The matrix $Q(t) \in \mathbb{R}^{N \times N}$ is symmetric positive definite for all $t \in [0, T]$, then there exist $\lambda_{\min}(t) > 0$ the minimum eigenvalue of $Q(t)$ such that

$$x'(t) Q(t) x(t) \geq \lambda_{\min}(t) \|x(t)\|^2, \quad \text{for all} \ t \in [0, T].$$

Definite the function $\lambda_{\min} : [0, T] \to \mathbb{R}$, such that

$$\lambda_{\min}(t) = \min \{\text{eigenvalue of Q(t)}\}.$$

Since all entry functions of $Q(t)$ are continuous, $\lambda_{\min}$ is a continuous function. Therefore, using the fact that $[0, T]$ is compact, there exist $\bar{\lambda} > 0$ such that

$$x(t)' Q(t) x(t) \geq \bar{\lambda} \|x(t)\| \ \forall t \in [0, T].$$

It follows from the definition of S_α that

$$
\begin{aligned}
\alpha &\geq \int_0^T \left(1/2x'(t)Q(t)x(t) + a'(t)x(t)\right) dt \\
&\geq \int_0^T \left(1/2\bar{\lambda}\|x'(t)\|^2 + a'(t)x(t)\right) dt \\
&\geq \int_0^T \bar{\lambda}/2\|x(t) + a(t)/\bar{\lambda}\|^2 - \int_0^T \|a(t)\|^2/2\bar{\lambda}dt.
\end{aligned}
$$

Since $a(t) \in BV([0,T], I\!R^N)$ then there exists $L \geq 0$ such that $L \geq \|a(t)\|^2$ and

$$
R = 2\alpha/\bar{\lambda} + TL^2/\bar{\lambda}^2 \geq \int_0^T \|x(t) + a(t)/\bar{\lambda}\|^2 dt \tag{4}
$$

Using again that $a(t) \in BV([0,T]; I\!R^N)$, it follows from (4) that S_α is bounded. It is now easy to see that the set $S_{n\alpha}$ is also bounded uniformly for $n \in \mathbb{N}$. $\square$

Example 4.1.   This example shows that the continuity of $Q(\cdot)$ to ensure the boundedness of the sub-level sets cannot be dropped out. Let

$$
Q(t) = \begin{cases} 1 & \text{if} \quad t = 0 \\ t & \text{if} \quad t > 0 \end{cases}
$$

and $B(t) = \sqrt{t}$, $K = 1$ and $c(t) = 1 + (1/2)t^{1/2}$. Clearly $Q(t)$ is of bounded variation and so are $B(\cdot)$ and $c(\cdot)$. Observe that the set

$$
S_1 := \left\{ x \in BV([0,T]; I\!R^N); \int_0^1 x'(t)Q(t)x(t)\, dt \leq 1 \right\}
$$

contains the unbounded sequence $\{x_n\}$ given by

$$
x_n(t) = \begin{cases} 0 & \text{if} \quad 0 \leq t < 1/n \\ 1/\sqrt{t} & \text{if} \quad 1/n \leq t \leq 1. \end{cases}
$$

Indeed,

$$
1 \geq \int_0^1 tx_n^2(t)\, dt = \int_{1/n}^1 dt = 1 - 1/n \quad \forall n.
$$

Moreover, a simple calculation shows that

$$B(t)x_n(t) - \int_0^t x_n(s)\,ds \le c(t) \quad \forall n,$$

proving the feasibility of x_n for all n. Therefore, the sub-level set S_1 of this example is unbounded, showing that the continuity of $Q(\cdot)$ cannot be left out.

Lemma 4.2. *Let $(x_n(t))$ and $(\theta_n(t))$ be the sequences generated from the optimal solutions x_n and θ_n of P_n e D_n, respectively. Then, there exist subsequences $(x_{n_k}(t))$ of $(x_n(t))$ and $(\theta_{n_k}(t))$ of $(\theta_n(t))$ which converge almost everywhere in $[0, T]$ to functions of bounded variation $\tilde{x}(t)$ and $\tilde{\theta}(t)$, respectively.*

Proof.   The proof follows immediately from Lemma 4.1 and Helly's Theorem ([7], Theorem 1.4.5).   □

We point out that the sequence of discretized problems (P_n) and related dual (D_n) are arbitrary. This implies that if we replace the sequences of problems (P_n) and (D_n) to subsequences $(P_{n'})$ and related dual $(D_{n'})$ in Lemma 4.2, and consider their respective sequences of optimal solutions $\{x_{n'}\}$ and $\{w_{n'}\}$ we can also extract convergent subsequences. The importance of this feature will be made clear in Remark 5.3.

We are now in position to state the main results of this section, which are Theorems 4.3 and 4.4. below. Theorem 4.3. states that the sequences of costs generated from sequences of continuous extensions of discrete optimal solutions converges to the costs of their limits, while Theorem 4.4 states that the adjusted costs of the discrete problems converge to the costs of the limits of sequences of the continuous extensions of the discrete optimal solutions. The proofs of both theorems are based on ideas taken from Buie and Abrham [1].

Theorem 4.3. *Let $(x_{n_k}(t))$ and $(\theta_{n_k}(t))$ be the subsequences obtained according to Lemma 4.2 and let $\tilde{x}(t), \tilde{\theta}(t)$ be their limits. Then*

a) $\displaystyle\lim_{n_k \to \infty} \int_0^T \left[(1/2)x'_{n_k}(t)Q(t)x_{n_k}(t) + a'(t)x_{n_k}(t) \right] dt$

   $= \int_0^T \left[(1/2)\tilde{x}'(t)Q(t)\tilde{x}(t) + a'(t)\tilde{x}(t) \right] dt;$

b) $\lim\limits_{n_k \to \infty} \int_0^T \left[-(1/2)\theta'_{n_k}(t)M(t)\theta_{n_k}(t) + N'(t)\theta_{n_k}(t) + R(t) \right] dt$

$= \int_0^T \left[-(1/2)\tilde{\theta}'(t)M(t)\tilde{\theta}(t) + N'(t)\tilde{\theta}(t) + R(t) \right] dt;$

c) $\tilde{x}(t)$ and $\tilde{\theta}(t)$ are feasible for (LQCTP) and (D), respectively.

Proof.   a) and b) follows from Helly's Theorem and Lebesgue dominated convergence theorem ([7], Theorem 6.2.10).

To prove part c), we first observe that $\tilde{\theta}(t) \geq 0$, since $\theta_{n_k}(t) \to \tilde{\theta}(t)$ almost everywhere in $[0, T]$ and $\theta_{n_k}(t) \geq 0$ almost everywhere in $[0, T]$, $\forall k \in \mathbb{N}$. The feasibility of $\tilde{x}(t)$ will follow if we prove that $\varepsilon(t) \leq 0$, where $\varepsilon(t) := \lim \varepsilon_k(t)$ almost everywhere in $[0, T]$ and

$$\varepsilon_k(t) := B(t)x_{n_k}(t) - \int_0^t K(t, s)x_{n_k}(s)\, ds - c(t)$$

and

$$\varepsilon(t) := B(t)x(t) - \int_1^t K(t, s)x(s)\, ds - c(t).$$

Let π_k be a partition of $[0, T]$ and let π_{k+1} be its refinement. Set $\pi := \cup_{k=1}^\infty \pi_k$.

Under hypothesis (H1), $\varepsilon_k(\cdot)$ is continuous almost everywhere in $[0, T]$ which implies $\varepsilon(\cdot)$ is also continuous almost everywhere in $[0, T]$. It follows, then, that $0 \geq \varepsilon(t) := \lim \varepsilon_k(t)$, $\forall t \in \pi$. It is also easy to see that $\pi = \cup_{k=1}^\infty \pi_k$ is dense in $[0, T]$. Let $\tilde{t} \in [0, T]$ be point of continuity of $\varepsilon(\cdot)$ and $\{t_j\} \subset \pi$ be a sequence such that $t_j \longrightarrow \tilde{t}$. This implies that $\varepsilon(\tilde{t}) \leq 0$ ($\varepsilon(\tilde{t}) = \lim_j \varepsilon(t_j) \leq 0$). $\square$

Theorem 4.4.   *Let $(x_{n_k}(t))$ and $(\theta_{n_k}(t))$ be subsequences obtained according to Lemma* 4.2 *and* $\tilde{x}(t)$, $\tilde{\theta}(t)$ *their limits. Then*

a) $(T/l_{n_i})[(1/2)x'_{n_k}Q_{n_k}x_{n_k} + a'_{n_k}x_{n_k}]$

$\to \int_0^T [(1/2)\tilde{x}'(t)Q(t)\tilde{x}(t) + a'(t)\tilde{x}(t)]dt, \text{ when } i \to \infty.$

b) $(T/l_{n_k})[-(1/2)\theta'_{n_k}M_{n_k}\theta_{n_k} + N'_{n_k}\theta_{n_k} + \theta_{n_k}]$

$\to \int_0^T [(1/2)\tilde{\theta}'(t)M(t)\tilde{\theta}(t) + N'(t)\tilde{\theta}(t) + R(t)]dt, \text{ when } i \to \infty.$

Proof.   a) For this proof we will introduce some additional notation

$$\tilde{x}_{n_k 0} = (1/2)\tilde{x}(0), \quad \tilde{x}_{n_k l_{n_k}} = (1/2)\tilde{x}(T) \quad \text{and} \quad \tilde{x}_{n_k i} = \tilde{x}(t_i^{n_k}),$$

$$i = 1, 2, \cdots l_{n_k} - 1; \quad \tilde{x}'_{n_k} = (\tilde{x}'_{n_k 0} : \tilde{x}'_{n_k 1} : \cdots : \tilde{x}'_{n_k l_{n_k}});$$

$$\tilde{x}_{n_k}(t) = (t - t_i^{n_k}/l_{n_k})(\tilde{x}_{n_k,i+1} - \tilde{x}_{n_k i}) + \tilde{x}_{n_k i}, \quad \text{for} \quad t_i^{n_k} \leq t \leq t_{i+1}^{n_k},$$

$$i = 0, 1, \cdots, l_{n_k} - 1; \text{(observe that } \lim_{n_k \to \infty} \tilde{x}_{n_k}(t) = \tilde{x}(t) \text{ a.e.)}.$$

$$a'_{n_k} = (a'_{n_k 0} : a'_{n_k 1} : \cdots : a'_{n_k l_{n_k}}) \quad \text{with} \quad a_{n_k 0} = a(0), a_{n_k l_{n_k}} = a(T) \quad \text{and}$$

$$a_{n_k j} = a(t_j^n) \quad \text{for} \quad j = 1, 2 \cdots, l_{n_k} - 1;$$

$$Q_{n_k} = \begin{pmatrix} Q_0^{n_k} & 0 & 0 & 0 & \cdots & 0 \\ 0 & Q_1^{n_k} & 0 & 0 & \cdots & 0 \\ 0 & 0 & Q_2^{n_k} & 0 & \cdots & 0 \\ \vdots & & & \ddots & & \vdots \\ 0 & \cdots & 0 & 0 & Q_{l_{n_k}-1}^{n_k} & 0 \\ 0 & \cdots & 0 & 0 & 0 & Q_{l_{n_k}}^{n_k} \end{pmatrix}.$$

Using the trapezoidal approximation in

$$\int_0^T \left[(1/2)\tilde{x}' Q(t)\tilde{x} + a'(t)\tilde{x}(t) \right] dt$$

and using above notation we see that

$$\int_0^T \left[(1/2)\tilde{x}' Q(t)\tilde{x} + a'(t)\tilde{x}(t) \right] dt$$
$$= \lim_{n_k \to \infty} (T/l_{n_k}) \left[(1/2)\, \tilde{x}'_{n_k} Q_{n_k} \tilde{x}_{n_k} + a'_{n_k} \tilde{x}_{n_k} \right].$$

It needs to be shown that

$$\lim_{n_k \to \infty} (T/l_{n_k}) \left[(1/2)(\tilde{x}'_{n_k} Q_{n_k} \tilde{x}_{n_k} - x'_{n_k} Q_{n_k} x_{n_k}) + a'_{n_k} (\tilde{x}_{n_k} - x_{n_k}) \right] = 0.$$

We have

$$\left| (T/l_{n_k}) a'_{n_k} (\tilde{x}_{n_k} - x_{n_k}) \right| \leq (T/l_{n_k}) \, \text{abs} \, (a'_{n_k}) \, \text{abs} \, (\tilde{x}_{n_k} - x_{n_k})$$

and

$$\left| (T/2l_{n_k})(\tilde{x}'_{n_k} Q_{n_k} \tilde{x}_{n_k} - x'_{n_k} Q_{n_k} x_{n_k}) \right| \leq (T/2l_{n_k}) \| \tilde{x}'_{n_k} \| \, \| Q_{n_k} \| \| (\tilde{x}_{n_k} - x_{n_k}) \|$$
$$+ (T/2l_{n_k}) \| \tilde{x}'_{n_k} - x'_{n_k} \| \, \| Q_{n_k} \| \, \| x_{n_k} \|.$$

Since $a(t)$ is bounded, there exists a constant $\lambda > 0$ such that abs $a_{n_k} \leq \lambda E$ for any n_k, where E is the vector with l_{n_k} components equal 1. We also have, because of the uniform bound on of $\| Q_{n_k} \|$, $\tilde{x}_{n_k}$ and x_{n_k}, that there exist constants α and β such that abs $(\tilde{x}'_{n_k} Q_{n_k}) \leq \alpha E$ e abs $(Q_{n_k} x_{n_k}) \leq \beta E$, for any n_k. Hence,

$$
\left| \frac{T}{l_{n_k}} a'_{n_k} (\tilde{x}_{n_k} - x_{n_k}) \right| \leq (T/l_{n_k}) \text{ abs } (a'_{n_k}) \text{ abs } (\tilde{x}_{n_k} - x_{n_k})
$$

$$
= \lambda \int_0^T E \text{ abs } (\tilde{x}_{n_k}(t) - x_{n_k}(t)) \, dt
$$

and

$$
\| (T/2l_{n_k})(\tilde{x}'_{n_k} Q_{n_k} \tilde{x}_{n_k} - x'_{n_k} Q_{n_k} x_{n_k}) \|
$$
$$
\leq \alpha E (T/2l_{n_k}) \text{ abs } (\tilde{x}_{n_k} - x_{n_k}) + \beta E (T/2l_{n_k}) \text{ abs } (\tilde{x}_{n_k} - x_{n_k})
$$
$$
= \alpha \int_0^T E \text{ abs } (\tilde{x}_{n_k}(t) - x_{n_k}(t)) \, dt + \beta \int_0^T E \text{ abs } (\tilde{x}_{n_k}(t) - x_{n_k}(t)) \, dt.
$$

It follows from *Lebesgue's* dominated convergence theorem that

$$
\lambda \int_0^T E \text{ abs } (\tilde{x}_{n_k}(t) - x_{n_k}(t)) \, dt \longrightarrow 0 \quad \text{for} \quad n_k \to \infty;
$$

$$
\alpha \int_0^T E \text{ abs } (\tilde{x}_{n_k}(t) - x_{n_k}(t)) \, dt \longrightarrow 0, \quad \text{for } n_k \longrightarrow \infty;
$$

and

$$
\beta \int_0^T E \text{ abs } (\tilde{x}_{n_k}(t) - x_{n_k}(t)) \, dt \longrightarrow 0, \quad \text{for } n_k \longrightarrow \infty.
$$

Therefore,

$$
\lim_{n_k \to \infty} \frac{T}{l_{n_k}} \left[(1/2) \left(\tilde{x}'_{n_k} Q_{n_k} \tilde{x}_{n_k} - x'_{n_k} Q_{n_k} x_{n_k} \right) + a'_{n_k} \left(\tilde{x}_{n_k} - x_{n_k} \right) \right] = 0.
$$

b) The proof of this part is similar to the proof of part (a).   □

5   Duality

In this section we discuss duality for LQCTP. It is a feature of our approach that the continuous dual problem contains no primal variable. Further, it is not of a

maxmin type. We show here that problem (D), as defined in Section 3, is in fact a dual of (LQCTP). The proof will follow from approximations of the continuous time pair of optimization problems by a finite dimensional ones whose duality theory is already known. Taking the limits we get the desired weak (Theorem 5.1) and strong (Theorem 5.2) duality results.

Theorem 5.1 [Weak Duality]. *If* $x(t)$ *and* $\theta(t)$ *are feasible solutions for Primal (LQCTP) and Dual (D) problems, respectively, then*

$$\int_0^T \left[(1/2)x'(t)Q(t)x(t) + a'(t)x(t)\right]dt$$

$$\leq \int_0^T \left[-(1/2)\theta'(t)M(t)\theta(t) + N'(t)\theta(t) + R(t)\right]dt.$$

Proof.   Let $x(t) \in BV([0, T]; \mathbb{R}^N)$ and $\theta(t) \in BV([0, T]; \mathbb{R}^{m+N})$ be feasible solutions of $LQCTP$ and D, respectively. Let π_n be a partition of the interval $[0, T]$ and $\{x_n\}$, $\{\theta_n\}$ be the values of $x(t)$ and $\theta(t)$ in the points of the partition π_n. It is easy to see that $\{x_n\}$, $\{\theta_n\}$ are feasible solutions of (P_n) and (D_n), respectively. Now, consider their continuous extensions $x_n(t)$ and $\theta_n(t)$ to the whole interval, as given by (2) and (3).

Because of Helly's convergence theorem [7], there exists $\tilde{x}(t), \tilde{\theta}(t)$ such that, $x_{n_k}(t) \to \tilde{x}(t), \theta_{n_k}(t) \to \tilde{\theta}(t)$, where $x_{n_k}(t)$, $\theta_{n_k}(t)$ are subsequences of $x_n(t), \theta_n(t)$, respectively.

We now show that $\tilde{x}(t) = x(t)$ and $\tilde{\theta}(t) = \theta(t)$ almost everywhere in $[0, T]$. Let $S := \{t \in [0, T] : x_{n_k}(t) \to \tilde{x}(t)\}$. S is dense in $[0, T]$. We also know that the set $\pi := \cup_{n=1}^\infty \pi_n$ is dense in $[0, T]$. Let $s \in \pi \cap S$. Then $s \in \pi_{n_0}$ for some n_0. This implies that $x_{n_k}(s) = x_{n_0}(s) = x(s)$ for all $n_k \geq n_0$. But $x_{n_k}(s) \to \tilde{x}(s)$. So, $x(s) = \tilde{x}(s)$. Since $s \in \pi \cap S$ is arbitrary it follows that $\tilde{x}(s) = x(s)$ almost everywhere in $[0, T]$. Analogously, we prove that $\tilde{\theta}(t) = \theta(t)$ almost everywhere in $[0, T]$.

By Theorem 4.2, it is known that

$$(T/l_{n_k})\left[(1/2)x'_{n_k} Q_{n_k} x_{n_k} + a'_{n_k} x_{n_k}\right]$$

$$\to \int_0^T \left[(1/2)x'(t)Q(t)x(t) + a'(t)x(t)\right]dt, \quad \text{for} \quad k \to \infty$$

and

$$(T/l_{n_k})\big[-(1/2)\theta'_{n_k}Q_{n_k}\theta_{n_k} + N'_{n_k}\theta_{n_k} + R_{n_k}\big]$$

$$\to \int_0^T \big[-(1/2)\theta'(t)Q(t)\theta(t) + N'(t)\theta(t) + R(t)\big]dt, \quad \text{for} \quad k \to \infty.$$

Since

$$(T/l_{n_k})\big[(1/2)x'_{n_k}Q_{n_k}x_{n_k} + a'_{n_k}x_{n_k}\big]$$

$$\leq (T/l_{n_k})\big[-(1/2)\theta'_{n_k}Q_{n_k}\theta_{n_k} + N'_{n_k}\theta_{n_k} + R_{n_k}\big], \ \forall \ i;$$

by [4] and taking the limit as $k \to \infty$, we obtain

$$\int_0^T \big[(1/2)x'(t)Q(t)x(t) + a'(t)x(t)\big]dt$$

$$\leq \int_0^T \big[-(1/2)\theta'(t)M(t)\theta(t) + N'(t)\theta(t) + R(t)\big]dt. \qquad \square$$

We now state the result that provides the optimality of the algorithm of discretization.

Theorem 5.2 [Strong Duality]. *Let $x(t) \in BV([0, T]; I\!R^N)$ and $\theta(t) \in BV([0, T]; I\!R^{m+N})$ be feasible solutions of $LQCTP$ and D, respectively, such that*

$$\int_0^T [(1/2)x'(t)Q(t)x(t) + a'(t)x(t)]dt$$

$$= \int_0^T [-(1/2)\theta'(t)M(t)\theta(t) + N'(t)\theta(t) + R(t)]dt.$$

Then, $x(t)$ and $\theta(t)$ are primal and dual optimal solutions, respectively.

Proof.   It is immediate from Theorem 5.1. $\square$

Remark 5.3. Under hypothesis (H1) the optima of the primal and the dual problems (LQCTP) and (D) are uniquely achieved (except on zero-measure set) at $x(t)$ and $\theta(t)$, respectively. This observation implies that the sequences (themselves) $\{x_n(t)\}$ and $\{\theta_n(t)\}$ generated by the optimal solutions of the discrete problems (P_n) and (D_n) converge to $x(t)$ and $\theta(t)$, almost everywhere.

To verify the second affirmation of Remark 5.3, take any subsequences $\{x_{n'}(t)\}$ and $\{\theta_{n'}(t)\}$ of $\{x_n(t)\}$ and $\{\theta_n(t)\}$, respectively. By Lemma 4.2 and Theorems 4.2 and 5.2 there exist further subsequences $\{x_{n_k'}(t)\}$ and $\{\theta_{n_k'}(t)\}$ that converge to the unique optimal solutions of (LQCTP) and (D), respectively. So, all subsequences have further subsequences that converge to the same limits. Therefore, the sequences (themselves) $\{x_n(t)\}$ and $\{\theta_n(t)\}$ converge to $x(t)$ and $\theta(t)$, respectively as required.

Remark 5.3 will be taken into consideration in the next section.

6   Karush-Kuhn-Tucker conditions (KKT)

The KKT conditions play no role in the convergence analysis of the approximating scheme we propose in this work. However, it is crucial in the process of obtaining analytical optimal solutions to compare the numerical experiments with.

On the other hand, the convergence set up provides the means from which it is possible to establish the KKT optimality conditions. Let us now state and prove them.

Proposition 6.1. *Suppose hypotheses* (H1)-(H3) *are in force. Let* $x(t)$ *be a function of bounded variation which minimizes LQCTP. Then there exists* w, λ : $[0, T] \to \mathbb{R}^n$, *functions of bounded variation such that*

1. $w(t), \lambda(t) \geq 0$ *a.e.* $t \in [0, T]$;

2. $\int_0^T \left[Q(t)x(t) + a' + B'(t)w(t) - \int_0^t K(s,t)w(s)ds - \lambda(t) \right] dt = 0$;

3. $w'(t) \left[B(t)x(t) - \int_0^t K(t,s)x(s) - c(t) \right] = 0$ *a.e.* $t \in [0, T]$;

4. $x'(t)\lambda(t) = 0$ *a.e.* $t \in [0, T]$.

Proof.   Let $x(t)$ minimize LQCTP and consider the discretized problem (P_n). Let x_n be the optimal solution of (P_n). By Proposition 3.1 there exist

$$w_n, \ \lambda_n : [0, T] \to I\!R^n,$$

such that

$$\theta_n, \ \lambda_n \geq 0;$$

$$\frac{T}{l_n}\big[Q_n x_n + a_n'\big]G_n' w_n - \lambda_n = 0; \tag{5}$$

$$w_n'\big(G_n x_n - c_n\big) = 0; \tag{6}$$

$$\lambda_n' x_n = 0. \tag{7}$$

Moreover, $\theta_n(t) := (w_n, \lambda_n)$ is the optimal solution of the discrete dual (D_n).

Let $x_n(t)$ and $\theta_n(t)$ be defined as in (2) and (3), respectively. As it was pointed out previously, $\theta_n(t)$ is a continuous time dual feasible solution, but $x_n(t)$ may not be. Nonetheless, because of Lemma 4.2, Theorems 4.4 and 5.2 we have that $x_n(t) \to x(t)$ and $\theta_n(t) \to \theta(t)$, where $x(t)$ and $\theta(t)$ are the unique solutions the continuous time primal and dual problems, respectively (except for a zero-measure set).

We are now in position to prove the KKT conditions for LQCTP. First, assertion 1. is satisfied, since $\theta(t)$ is dual feasible. To prove assertions 2., 3. and 4. consider

$$\epsilon_n := \int_0^T \big[Q(t)x_n(t) + a' + B'(t)w_n(t)$$
$$- \int_0^t K(s,t)w_n(s)ds - \lambda_n(t)\big]dt; \tag{8}$$

$$e_n(t) := w_n(t)\big[B(t)x_n(t) - \int_0^t K(t,s)x_n(s) - c(t)\big]$$
$$\text{a.e. } t \in [0,T]; \tag{9}$$

$$\rho_n(t) := x_n(t)\lambda_n(t) \quad \text{a.e. } t \in [0,T]. \tag{10}$$

Since $\theta_n(t) \to \theta(t)$ and $x_n(t) \to x(t)$ almost everywhere, the right sides of (8), (9) and (10) converge to the left sides of 2., 3. and 4. (The first convergence relies on the Lebesgue dominated convergence theorem). The proof will be complete if we prove that whenever π_{n+1} is a refinement of π_n, for every n, we have $\epsilon_n \to 0$, $e_n(t) \to 0$ and $\rho_n(t) \to 0$, as $n \to \infty$.

The proofs that $\rho_n(t)$ and $e_n(t)$ converge to zero almost everywhere follow from (6) and (7) by making use of arguments similar to those of the proof of Theorem 4.3 (c).

To prove that ϵ_n goes to zero as $n \to \infty$ we use (5) and arguments similar to the proof of Theorem 4.4 (a) and (b).

7 Examples

In this section we provide a series of examples to show that our approach is reasonable to solve difficult problems in the LQCTP class. To make sure our approach gives a good approximate solution, we selected some examples, where the analytical optimal solutions can be obtained, with the help of Proposition 6.1, and compare the numerical solutions with the analytical ones.

We solved analytically a family of problems with varying parameters. Optimality of candidates was checked via KKT conditions. Then we solved numerically the same family of problems, making use of the proposed scheme of approximation and verified that the numerical solutions approximated very well the analytical true solutions of the problems in consideration.

In order to calculate the numerical solutions to make sure our theory works in practice, we solved the discretized quadratic problems with the commercial packaged CPLEX 4.0. in a 700MHz PC-pentium III, with 128MB of RAM.

A comparison between the analytical solutions and the numerical ones, which were obtained for partitions of 1600 points of the interval, gave an approximation no greater than 10^{-6}, using the L^1-norm.

For easy of understanding and visual comparisons, we plotted the graphs of the analytical and the numerical solutions in the same place, see Figures 1-5. For each particular example, we chose to plot only a sample of points of the numerical solution because, had we chosen to plot the numerical solution along aside with analytical solution, using a great quantity of points, the two curves would have merged.

It is also worth noting that in each figure, the drawing on the left is for x_1, the first component of the optimal solution, while the drawing on the right is for x_2.

The five examples we explore here are, in fact, a family of problems parameterized by $(\alpha, \beta)'$, that we introduce now.

$$\text{Minimize} \quad \int_0^T \left[\frac{1}{2} x'(t) \begin{pmatrix} 2 & 1 \\ 1 & 2 \end{pmatrix} x(t) - (6,\ 6)\, x(t) \right] dt$$

$$\text{Subject to} \quad \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} x(t) - \int_0^t \begin{pmatrix} 2 & 0 \\ 0 & 2 \end{pmatrix} x(t) dt \le \begin{pmatrix} \alpha \\ \beta \end{pmatrix}$$

$$x_1(t), \ x_2(t) \ge 0.$$

By using Proposition 6.1, we calculate the analytical solutions, for each case below. Observe that we make changes on the values of the parameters α and β in each example. In the first four examples the analytical solutions are continuous functions. In Example 7.5 the optimal solution contains discontinuous functions, see Figure 5. It can be observed in Figures 1, 2, 3, 4 and 5 that the graphs of the numerical and the analytical solutions are visually the same.

Example 7.1. If $\alpha \ge 2$ and $\beta \ge 2$, then $x_1(t) = 2$ and $x_2(t) = 2$ are optimal solutions.
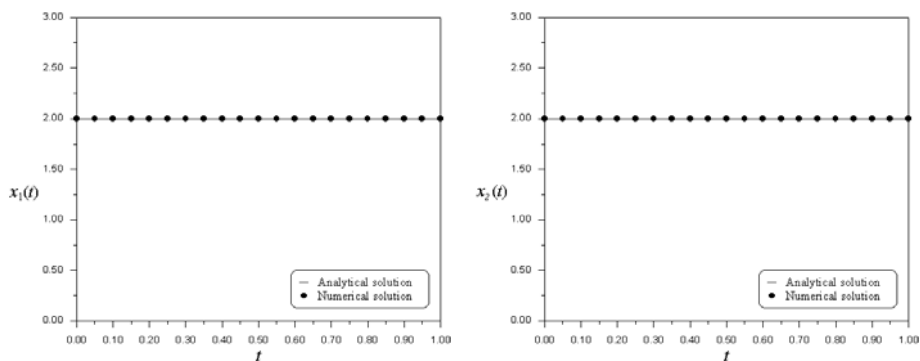

Figure 1

Example 7.2. If we make $2\alpha + \beta \le 6$ with $\alpha > \beta, 0 < \beta < 2$; the following analytical solution has been obtained:

$$x_1(t) = \begin{cases} \alpha \exp(2t), & 0 \le t \le (1/2)\ln(6/(2\alpha + \beta)), \\ 3 - (\beta/2)\exp(2t), & (1/2)\ln(6/(2\alpha + \beta)) \le t \le (1/2)\ln(2/\beta), \\ 2, & (1/2)\ln(2/\beta) \le t \le 1; \end{cases}$$

$$x_2(t) = \begin{cases} \beta \exp(2t), & 0 \le t \le (1/2)\ln(2/\beta), \\ 2, & (1/2)\ln(2/\beta) \le t \le 1. \end{cases}$$
Figure 2

Example 7.3.   If $2\alpha + \beta > 6$ with $\alpha > \beta, 0 < \beta < 2$, the following analytical solution has been obtained:

$$x_1(t) = \begin{cases} 3 - (\beta/2)\exp(2t), & 0 \le t \le (1/2)\ln(6/\beta), \\ 2, & \ln(6/\beta) \le t \le 1. \end{cases}$$

$$x_2(t) = \begin{cases} \beta\exp(2t), & 0 \le t \le (1/2)\ln(2/\beta) \\ 2, & (1/2)\ln(2/\beta) \le t \le 1. \end{cases}$$

Figure 3

Example 7.4. If $\alpha \geq 2$ and $\beta = 0.0$; the following analytical solution has been obtained:

$$x_1(t) = \begin{cases} \alpha \exp(2t) & \text{if } 0 \leq t \leq 0.5 \ln(3/\alpha), \\ 3 & \text{if } 0.5 \ln(3/\alpha) \leq t \leq 1. \end{cases}$$
and $x_2(t) \equiv 0$.

Figure 4

Example 7.5. In this example take function $c(t)$ to be the vector $(\alpha, \beta)'$, where

$$\alpha = \begin{cases} \alpha_0 & \text{if } 0 \leq t \leq t_0, \\ \alpha_1 & \text{if } t_0 \leq t \leq t_1, \end{cases} \quad \text{and} \quad \beta = \begin{cases} \beta_0 & \text{if } 0 \leq t \leq t_0, \\ \beta_1 & \text{if } t_0 \leq t \leq t_1. \end{cases}$$

Now, consider the following numbers

$$t_1 = 0.5 \ln(6/(2\alpha_0 + \beta_0)), \qquad t_2 = 0.5 \ln(6/(2\bar{\alpha} + \bar{\beta})) + t_0,$$
$$t_3 = 0.5 \ln(6/(\bar{\alpha} + 2\bar{\beta})) + t_0, \quad t_4 = 0.5 \ln(2/(\bar{\beta})) + t_0,$$
$$t_5 = 0.5 \ln(2/\bar{\alpha}) + t_0,$$

where

$$\bar{\alpha} = \alpha_1 + 2 \int_0^{t_0} x_1(t)dt \quad \text{and} \quad \bar{\beta} = \beta_1 + 2 \int_0^{t_0} x_2(t)dt.$$

Taking $\alpha \geq \beta$, $2\alpha_0 + \bar{\beta} \leq 6$, $t_0 \leq t_2$, $t_3 \geq t_4$, $2\bar{\alpha} + \bar{\beta} \leq 6$, the following analytical solution has been obtained:

$$x_1(t) = \begin{cases} \alpha_0 \exp(2t), & 0 \leq t \leq t_0, \\ \bar{\alpha} \exp(2(t - t_0)), & t_0 \leq t \leq t_2, \\ 3 - (\beta/2) \exp(2t), & t_2 \leq t \leq t_4, \\ 2, & t_4 \leq t \leq 1. \end{cases}$$

$$x_2(t) = \begin{cases} \beta \exp(2t), & 0 \leq t \leq t_4, \\ 2, & t_4 \leq t \leq 1. \end{cases}$$

The values for which this example works are $\alpha_0 = 1$, $\alpha_1 = 0.5$, $\beta_0 = \beta_1 = 0.5$, and $t_0 = 0.25$.

Figure 5

8   Final consideration

In this work we consider a general class of LQCTP and proposed a computational scheme that is able to provide, via interpolation, a nearby continuous time optimal solution. We show through examples that in a number of cases it is possible to actually find an analytical optimal solution of the problem. We also established weak and strong duality results for this class of problems in which the dual problems contain only dual variables as opposed to minmax formulation of duality. For the purpose of checking the optimality of candidates of analytical solutions we provided the so called Karush-Kuhn-Tucker conditions

of optimality. The proof of these conditions relies on finite dimensional Karush-Kuhn-Tucker conditions and the analysis of convergence of continuous solutions obtained from the optimal solution of the discrete approximating problems. In our set of examples it becomes clear that the proposed approximating scheme for linear quadratic continuous time problems works well.

However, some questions remain unanswered. 1) Is it possible to relax the positive definiteness of Q in the quadratic integral cost? 2) Is it possible to generalize the method employed here to address general nonlinear continuous time convex problems?
