

Lycopodiaceae in Brazil. Conspectus of the family II. The genera *Lycopodiella*, *Palhinhaea*, and *Pseudolycopodiella*

Benjamin Øllgaard^{1,3} & Paulo G. Windisch²

Abstract

This paper treats the Brazilian species of three genera of the Lycopodiaceae: *Lycopodiella* with four species (one endemic), *Palhinhaea* with six (two endemics), and *Pseudolycopodiella* with seven (one endemic). The species are described, and keys and illustrations, or references to illustrations for their identification are provided. The nomenclature is reviewed. Representative specimens are cited, and the general distribution and habitats are indicated. *Pseudolycopodiella squamata* is described as new to science.

Key words: diversity, floristics, lycophytes, phytogeography, taxonomy.

Resumo

Este trabalho trata as espécies de três gêneros de Lycopodiaceae: *Lycopodiella* com quatro espécies (uma endêmica), *Palhinhaea* com seis (duas endêmicas) e *Pseudolycopodiella* com sete (uma endêmica). As espécies são descritas, sendo apresentadas chaves e ilustrações ou referências a ilustrações para sua identificação. A nomenclatura está revisada, espécimes representativos são citados, a distribuição geral e habitats são indicados. *Pseudolycopodiella squamata* é descrita como nova para a ciência.

Palavras-chave: diversidade, florística, licófitas, fitogeografia, taxonomia.

Introduction

This is the second part of a series of treatments of the Brazilian Lycopodiaceae. It deals with the genera *Lycopodiella*, *Palhinhaea*, and *Pseudolycopodiella*, including a total of 17 species. The first part (Øllgaard & Windisch 2014) treated the genera *Austrolycopodium*, *Diphasiastrum*, *Diphasium*, and *Lycopodium*, including five species, and gave a general introduction to the family, the history of its study and exploration in Brazil, and keys to the genera of the whole family.

The three genera treated here correspond to the subfamily Lycopodielloideae of Wagner & Beitel (1992), validated by Øllgaard (2014), and the genus *Lycopodiella* Holub *s. lat.* (*sensu* Øllgaard 1987).

In addition to these three genera, the genus *Lateristachys* Holub (1983) (Australia, New Zealand, Tasmania, New Caledonia, and the Philippines) belongs to the Lycopodielloideae.

Material and Methods

The methodology used in this study was the same adopted by the first part of this treatment (Øllgaard & Windisch 2014).

Taxonomic treatment

The genera treated in the present study can be distinguished from the remaining of Lycopodiaceae genera occurring in Brazil based on the characters presented in the following key.

¹ University of Aarhus, Institute for Bioscience, build. 1137, DK 8000 Aarhus C., Denmark.

² Universidade Federal do Rio Grande do Sul, Inst. Biociências, PPG Botânica, 91501-970, Porto Alegre, RS, Brazil.

³ Author for correspondence: benjamin.øellgaard@biology.au.dk

Key to Brazilian genera of Lycopodiaceae

1. Stems isotomously branched throughout, without elongate, indeterminate main stems, but sometimes heteroblastic, roots usually forming one basal tuft, sporophylls and vegetative leaves alike, or the sporophylls, if smaller, persisting and green, not subpeltate and ephemeral; spores foveolate-fossulate *Huperzia* and *Phlegmariurus*
- 1'. Stems anisotomously branched throughout, the branches differentiated into elongate, indeterminate, rhizomatous, or creeping, trailing, or climbing main stems, and usually determinate branchlet systems; sporophylls strongly modified, ephemeral, unlike vegetative leaves, peltate or subpeltate, aggregated in compact, terminal strobili.
 2. Strobili erect, sessile or pedunculate, borne on branchlet systems which arise in a dorso-lateral position on the main stem; side walls of sporangium epidermis cells sinuate, lignified throughout; spores reticulate..... *Austrolycopodium*, *Diphasiastrum*, *Diphasium*, and *Lycopodium*
 - 2'. Strobili pendulous and sessile, - or strobili erect and terminating simple or to twice forked branches which arise dorsally on the creeping stem (but see *Palhinhaea bradei*); sidewalls of sporangium epidermis cells straight, non-lignified, except for nodular or semi-annular lignified thickenings; spores rugate.
 3. Strobili pendent or nodding, terminating amply branched branchlet systems which are borne on an erect or scandent-trailing, tree-like main branch, - or rarely (*P. bradei*) strobili ascending, borne on low, ascending, somewhat fan-shaped branchlet systems, lacking an erect main branch; sporangia remaining partly enclosed in cavities formed by the strobilus cortex and coalescent membranous bases of adjacent sporophylls; sporangium walls with nodular lignified thickenings *Palhinhaea*
 - 3'. Strobili erect, terminating simple or forked erect branches (peduncles) that arise dorsally on the creeping stem; sporophylls free, sporangia not enclosed in cavities at maturity. Sporangium walls with semiannular lignified thickenings.
 4. Sporophylls nearly twice as wide as adjacent peduncle leaves or wider, ovate to ovate-lanceolate, of different colour and texture than peduncle leaves, the margins minutely rugose to minutely fimbriate-denticulate, usually to 10 (–12)-seriate; sporangia isovalvate, attached to the upper side of the sporophyll; creeping shoots isophylloous to strongly anisophylloous, with wide and long lateral leaves and narrow dorsal leaves; sporangium epidermis cells with incompletely lignified semiannular thickenings *Pseudolycopodiella*
 - 4'. Sporophylls slightly wider to ca. 1.5 times wider than adjacent peduncle leaves and of the same colour and texture, linear-lanceolate to ovate- lanceolate, with few to several sharp, long and often recurved teeth, (10–) 12–20-seriate; sporangia anisovalvate, axillary; creeping shoots isophylloous or nearly so; sporangium epidermis cells with completely lignified semiannular thickenings *Lycopodiella s. str.*

Lycopodiella Holub s. str., Preslia 36: 22. 1964. - Type: *Lycopodiella inundata* (L.) Holub (= *Lycopodium inundatum* L.).

Lycopodium subgen. *Rhopalostachya* Pritzel sect. *Inundata* Pritzel, Nat. Pflanzenfam. 1(4): 601. 1901. - *Lycopodium* subgen. *Lycopodiella* (Holub) B. Øllg., Amer. Fern J. 69: 49. 1979. - *Lycopodium* subgen. *Inundatistachys* Herter, Bot. Jahrb. 43: Beibl. 98: 29. 1909.

Sporophytes with prostrate or looping, rooting, indeterminate stems, isophylloous to slightly anisophylloous, horizontally branching shoots, and dorsally arising, erect, simple or to three times forked

strobiliferous branches; leaves of erect branches conform with leaves of prostrate shoots, or somewhat reduced; sporophylls arranged in alternating whorls of 5 or more, forming 10 or more longitudinal ranks, free, not enclosing the sporangia in cavities at maturity, subpeltate, with triangular cross-section of the immature stalk, with veinal and basal mucilage canals; sporangia axillary, transversely oblong, with a narrow stalk, anisovalvate; sporangium epidermis cells with semiannular, lignified thickenings; $x = 78$.

Northern temperate regions, Tropical America south to Northern Argentina. Twelve or more species. Several interspecific hybrids are known in North

America, where the hybrids between homoploid species form normal spores (Bruce 1975). The sporophylls of *Lycopodiella* have been repeatedly indicated to be similar to the leaves, and the genus was therefore assumed to be more primitive than those of the other strobiliferous groups (e.g., Pritzel 1901). Their similarity is only superficial, however. The sporophylls have a distinctly subpeltate base, containing a well developed basal mucilage canal (Bruce 1976).

The South American representatives of the genus were earlier referred to *Lycopodiella*

alopecuroides (L.) Holub, but this species sensu stricto is limited to North America and Cuba.

Nessel (1927, 1955) treated the Brazilian material under *Lycopodium alopecuroides* with several varieties. However, few of these were based on relevant features, and some were included in the Brazilian flora on the basis of mislabelled North American material in his private herbarium. Nessel included all Brazilian material belonging in *Lycopodiella* in one species, and in 1927 also *Pseudolycopodiella contexta*, following Christ (1902).

Key to the species of *Lycopodiella* in Brazil

1. Main horizontal stem arching to looping, rooting with long intervals at soil contact, or rarely partly creeping and rooting closely; the laterally arising minor branchlet systems ascending to erect, subequally forking, with ascending to appressed leaves throughout; strobiliferous branch simple or to 3 times forked *Lycopodiella geometra*
- 1'. Main horizontal stem and its minor branches closely appressed to the ground, with patent-ascending to perpendicular, often slightly anisophyllous leaves; strobiliferous branch simple (rarely forked, or the strobilus rarely branched).
 2. Strobili 15–25 mm thick incl. sporophylls, sporophylls 9–13 mm long, vegetative leaves of erect branch 8–10 mm long *Lycopodiella duseniana*
 - 2'. Strobili 6–15 mm thick incl. sporophylls, sporophylls 3.5–9 mm long, vegetative leaves of erect branch 4–7 mm long.
 3. Strobili with spreading to loosely appressed, linear-lanceolate to lanceolate, 5–7 (–9) mm long sporophylls, 8–15 mm thick incl. sporophylls; leaves of horizontal shoots with smooth to long-ciliate or coarsely dentate margins *Lycopodiella longipes*
 - 3'. Strobili with loosely to closely appressed, lanceolate to ovate and cuspidate, 3.5–6 mm long sporophylls; 5–10 mm thick incl. sporophylls, leaves of horizontal shoots with smooth to minutely denticulate margins *Lycopodiella tupiana*

Lycopodiella duseniana (B. Øllg. & P.G. Windisch) B. Øllg., Rodriguesia 63: 479. 2012.

Fig. 1

Lycopodiella alopecuroides var. *duseniana* B. Øllg. & P.G. Windisch, Bradea 5: 29, fig. 4d. 1987. - Type: Brasil: estado do Rio de Janeiro, Itatiaia, Retiro, P. Dusén 165 (S holotype).

Illustrations: Nessel, in Hoehne, Fl. Bras. fasc. 11 (II:II): 97, fig. 79. 1955, as *Lycopodium alopecuroides* var. *juergensii* Rosenst.

Horizontal shoot system creeping, rooted with short intervals, bearing laterally arising, sparsely ramified dichotomous branchlet systems, and dorsally arising, stiffly erect, simple, to 25 (–35) cm tall strobiliferous branches. Main branch of horizontal shoot system to at least 40 cm long, covered by patent to loosely upward curved leaves, 8–18 mm diam. incl. leaves,

1.5–3 mm thick excl. leaves. Leaves of creeping branches usually flat, often somewhat upward secund, linear-subulate, 5–10 × ca. 0.7–1 mm, with smooth margins. Strobiliferous branches with patent-ascending to somewhat appressed leaves, ca. 5–15 mm diam. incl. leaves, 1.5–2.5 mm thick excl. leaves. Leaves of strobiliferous branches borne in irregular, alternating low spirals or whorls of 5–7, forming 10–14 indistinct longitudinal ranks, essentially conform with those of horizontal main branch, or sometimes with a few long spreading teeth. Strobili 6–13 × 1.5–2.5 cm incl. sporophylls. Sporophylls borne in alternating whorls of 7–9, forming 14–18 indistinct longitudinal ranks, linear-lanceolate to lanceolate, with coarse pluricellular, spreading to hooked teeth on the margin, 7–12 × 1–1.2 mm. Sporangia ca. 1 mm wide.

Collections studied: BRAZIL. MINAS GERAIS: Parque Nacional do Caparaó, 2000 m, Krieger et al. (CESJ 24180). RIO DE JANEIRO: Serra dos Órgãos, Campo de Antas, 2000 m, Rizzini 663 (RB). Itatiaia, trilha para o Pico das Agulhas Negras, 2400 m, Condack, 410 (RB). PARANÁ: Capão Grande, Dec. 1903, Dusén (S).

Distribution and habitat: Endemic to Southeastern and Southern Brazil. States of Minas Gerais, Rio de Janeiro, Paraná. Limited to wet, grassy high-altitude communities, campo do altitude. 2000–2400 m.

Differs from *Lycopodiella longipes* by its generally shorter strobiliferous branches (to ca. 30 cm tall) and stouter growth habit, longer, and wider, entire, vegetative leaves, thick strobili, and long sporophylls.

Type: Brazil: Est. Minas Gerais: mun. Santana do Riacho, estrada de Lagoa Santa a Conceição do Mato Dentro, Km 132 (antigo), Serra do Cipó, campo rupestre, entre gramíneas, alt. ca. 1250 m, 2 Feb. 1987, J. Prado et al. 80 (HB holotype, AAU, SP, SPF isotypes).

Lycopodium alopecuroides L. var. *furcatum* Fée, Crypt. vasc. Brésil. I: 223. 1869. - Type: Warming s.n., Brazil, Minas Gerais, Lagoa Santa, 1866 (C).

Lycopodium alopecuroides L. var. *hoehneanum* Nessel, Arch. Bot. Est. S. Paulo 1: 430, t. 37. 1927. - Types: 6 collections from SP cited: Hoehne s.n., Brazil, São Paulo, Pinheiros, 30/8/917 (SP 469, lectotype, here selected, illustrated in protologue).

Illustrations: Nessel in Hoehne, Fl. Bras. fasc. 11 (II:II): 1955: fig. 85, 86, 89, as *Lycopodium alopecuroides* var. *longipes*, and *L. alopecuroides* var. *hoehneanum*.

Horizontal shoot system arching to looping, rooted with long intervals at soil contact, or partly creeping and rooting closely, bearing laterally arising, erect, to several times subequally forked branchlet systems, and dorsally arising, stiffly erect, simple or to 3 times subequally dichotomous, at least to 50 cm tall strobiliferous branches. Main branch of horizontal shoot system to at least 70 cm long, covered by ascending to loosely appressed leaves, (4–) 5–10 mm diam. incl. leaves, 2.5–6 (–10) mm thick excl. leaves, inundated stem portions often swollen. Main branch leaves usually flat, subulate, 5–8 × ca. 0.8–1 mm, with coarse, spreading to hooked marginal teeth. Laterally arising erect branchlet systems at least to 25 cm high, to at least 4 times dichotomous. Ultimate branchlets 3–8 mm diam. incl. leaves, 0.7–1.5 mm diam. excl. leaves. Branchlet leaves ascending, arcuate-ascending to arcuate-appressed, densely crowded, concealing the stem, subulate, usually abaxially convex, (2.5–) 4–6 × 0.5–0.8 (–1) mm, with few (or some without) to many spreading teeth, often with a slightly thickened, pale, smooth apex. Strobiliferous branches with uniformly appressed leaves, 5–10 mm diam. incl. leaves, 2–5 mm thick excl. leaves, borne in irregular, alternating low spirals or whorls of 8–10, forming 16–20 indistinct longitudinal ranks, essentially conform with those of horizontal main branch. Strobili to 18 cm long, 8–20 mm diam. Sporophylls borne in

Figure 2 – *Lycopodiella geometra*. Brazil, São Paulo, Pinheiros, Brade 8214 (HB).

alternating whorls of 6–10, forming 12–20 indistinct longitudinal ranks, with narrow transverse and basiscopic wings on the stalk, linear-lanceolate to lanceolate, with coarse pluricellular, spreading to hooked teeth on the margin, (4–) 5–10 × 1–1.5 (–2) mm. Sporangia ca. 1 mm wide.

Reference specimens (more than 80 collections studied, complete listing available from the main author): BRAZIL. BAHIA: Löfgren 510 (S). MATO GROSSO: Tapirapoan, Hoehne 1487 (R). Vila Ema-São Caetano, Brade 15693 (AAU, RB). Campos do Jordão, Lanstyck (RB 33090). Serra da Bocaina, Fazenda Bonito, Lutz, A. 528 (R).

Distribution and habitat: Central Brazilian highlands to Paraguay and Argentina (prov. Corrientes). States of Bahia, Mato Grosso, Minas Gerais, Rio de Janeiro, São Paulo, Paraná, Santa Catarina, Rio Grande do Sul. Terrestrial, wet or humid, open places in campo vegetation, alt. 500–1300 m.

The branching morphology of this species is variable. The erect, strobiliferous branches vary from simple to 3 times forked in the same population. The size of strobili varies, partly in correlation with the number of dichotomies of the strobiliferous branch; a simple one usually has a very large strobilus with ca. 20 rows of sporophylls, whereas the strobili of forked branches usually are smaller and with 12–14 rows. Rarely one of the vegetative branchlets may develop into a new horizontal main branch (Heiner 638, S).

Table 37 in Nessel (1927) is a good illustration of the growth habit of the species.

Hetschbach 29056 (MBM) has a creeping horizontal branch rooting with intervals of 1–3 cm, and has a simple strobiliferous branch, and thus

resembles *L. longipes*, however, the lateral branches of the creeping stem are erect and with appressed leaves, so belongs to *L. geometra*.

Lycopodium alopecuroides L. var. *nettoanum* Glaziou ex Baker, Handb. fern allies 19. 1887: 19. Type: not designated; a Glaziou collection presumably at K to be selected. According to the description this is an obviously a synonym of *L. geometra*, but no type was found at K so far.

Lycopodium alopecuroides L. var. *juergensii* Rosenst. (Hedwigia 46: 165. 1907). Type: Juergens & Stier n. L 33, not seen, Rio Grande do Sul, Cruz Alta, probably belongs to *L. geometra* as indicated by the features mentioned in the protologue to be diagnostic.

The illustrations in Nessel (1955, fig. 79) for var. *juergensii* show *L. duseniana*.

No valid description of *Lycopodium heterocaulon* Silveira has been found. Material so annotated by Silveira (P), and by Christ (Silveira 292 P-herb. Christ) belongs to *L. geometra*.

As indicated by the synonymy above this species has been recognized as a taxon at variety level by several authors, but it is indeed a very distinctive species. We have seen it growing together with *Lycopodiella longipes* under uniform conditions, maintaining the distinctive features indicated in the key.

Lycopodiella longipes (Grev. & Hooker) Holub, Fol. Geobot. Phytotax. 26: 93. 1991. Fig. 3

Lycopodium longipes Grev. & Hook., Bot. Misc. 2: 372. 1831. - *Lycopodium alopecuroides* L. var. *integerrimum* Spring, Mém. Acad. Roy. Sci. Belg. 15: 75. 1842. - *Lycopodium alopecuroides* L. var. *longipes* (Grev. & Hook.) Rosenst., Hedwigia 46: 165. 1907. - Type: Brazil, Island of St. Catherine, Macrae s.n (E! holotype, K! isotype).

Lycopodium alopecuroides L. var. *pseudoreflexum* Christ, Bull. Herb. Boiss. ser. 2, 2 (8): 706. 1902. - Type: Glaziou s.n. (P-herb. Christ).

Lycopodium alopecuroides L. var. *divaricatum* Nessel, Arch. Bot. Est. S. Paulo 1: 425. 1927. - Type: Mendonça 1412, Brazil, Rio de Janeiro, Nova Friburgo, campos turfosos, distantes da cidade [BONN-herb. Nessel 23; (no type material was found in London as cited)]. - Note: Nessel attributed this variety to Rosenstock, who had distributed an exsiccatum [Rio Grande do Sul: Porto Alegre, Cascadas, Stier, in Rosenst., Fil. austrobras. exsicc. 251 (BM, E, M, P, S)] under this name. The name was validly published by Nessel, but based on other specimens, as cited above.

Lycopodium alopecuroides L. var. *rigidum* Nessel, Arch. Bot. Est. S. Paulo 1: 425. 1927. - Syntypes: Ule s.n., Brazil, Goyas: Imediações da Cachoeira de San Antonio, baixadas humidas (R, not seen); F.C. Hoehne 5161, Brazil, Miguel Burnier, 27/1/921 (SP, lectotype, here selected). - Note: Nessel intended to base this variety on *Lycopodium inundatum* L. var. *rigidum* Spring (1838: 167–168), which was not validly published. Further, Spring's material (Brasil, Ackermann, Herb. Martius (M, not seen, BR, a mixed collection containing a fragment of *Lycopodium clavatum*, and an erect strobiliferous branch of *Lycopodiella longipes*) was not cited by Nessel.

Horizontal shoots appressed to the ground, firmly rooted with short intervals, at least to 50 cm long, unequally branched in the horizontal plane, densely covered on all sides by almost uniform or slightly anisophyllous, somewhat upwardly secund, or spreading to perpendicular leaves, (6–) 10–15 mm wide incl. leaves, 1–3 mm thick excl. leaves, the stem surface and leaf bases sometimes provided with few to many pluricellular hairs. Leaves of horizontal shoots

narrowly lanceolate or subulate to linear, flat, with smooth to denticulate or long-ciliate margins, soft, light green, 5–7 (–8) × 0.5–1 (–1.2) mm. Ventral leaves of horizontal shoots conform to only half as wide as lateral and dorsal leaves. Erect branches simple or rarely once forked, at least to 45 cm tall, ca. 4– ca.10 mm diam. incl. leaves, 1–2 (–2.5) mm thick excl. leaves, its leaves radially arranged, borne in alternating whorls of 6–10, ca. 1.5–3 mm apart, forming 12–20 indistinct longitudinal ranks, essentially like leaves of horizontal shoots, sometimes slightly narrower or with more dentate-ciliate margins, usually ascending to closely appressed. Strobili at least to 16 cm long, sometimes abruptly forked, 8–15 mm diam. incl. sporophylls. Sporophylls arranged as peduncle leaves, linear-lanceolate to widely lanceolate from a subpetiolate base, with few to many, coarse, spreading to hooked teeth on margins, 5–7 (–9) × 1–1.5 (–2) mm. Sporangia ca. 1 mm diam.

Distribution and habitat: Tropical South America except the Andes south to Argentina (Corrientes), and Uruguay. Brazil: State of Acre, Roraima, Amazonas, Pará, Rondônia, Bahia, Goiás, Distrito Federal, Mato Grosso, Mato Grosso do Sul, Minas Gerais, Espírito Santo, Rio de Janeiro, São Paulo, Paraná, Santa Catarina, Rio Grande do Sul. Open, moist localities on sandy and clayey soil, banks of rivers and roads, brejos, wet grassland, from sea level to 2300 m.

Lycopodiella tupiana (B. Øllg. & P.G. Windisch) B. Øllg., *Rodriguesia* 63: 480. 2012. Fig. 4.

Lycopodiella alopecuroides var. *tupiana* B. Øllg. & P.G. Windisch, *Bradea* 5: 30, fig. 4b. 1987. - Type: Brasil: Estado São Paulo, Peruibe (litoral Sul do estado), margem da rod. Pe. Manoel da Nobrega, entre Itanhaém e Peruibe, Km 120, no solo arenoso, juntamente com *L. carolinianum*, 4 Mar 1972, B. Siegel 6 (HB holotype).

Horizontal shoots appressed to the ground, firmly rooted with short intervals, at least to 40 cm long, unequally branched in the horizontal plane, densely covered on all sides by almost uniform or slightly anisophyllous, somewhat upwardly secund, or spreading to perpendicular leaves, (6–) 10–15 mm wide incl. leaves, 1–2 mm thick excl. leaves (dried). Leaves of horizontal shoots narrowly lanceolate or subulate, flat, with smooth margins, soft, light green, 5–6 (–8) × ca. (0.5–) 1 mm. Ventral leaves of horizontal shoots conform to only half as wide as lateral and dorsal leaves. Erect branches simple, 10–40 cm tall, 3–5 (–8) mm diam. incl. leaves, 1.5–2 mm thick excl. leaves, its leaves radially arranged, borne in alternating whorls of 5–6 (–7), forming 10–12 (–14) indistinct longitudinal ranks, usually lanceolate, 4–5 × 0.5–0.8 (–1) mm, often with dentate-ciliate margins, usually ascending to closely appressed. Strobili to 12 × 0.5–1 cm. Sporophylls arranged as peduncle leaves, lanceolate to ovate-long-cuspidate from a subpetiolate base, with few to many, coarse, spreading to hooked teeth on margins in the basal half, (3–) 4–5 (–6) mm long at maturity, 1–1.5 mm wide at base. Sporangia ca. 1 mm diam.

Reference specimens (more than 25 collections studied, complete listing available from the main author): PARANÁ: Jacareí, *Dusén* 16756 (S), 17491 (NY, S). RIO GRANDE DO SUL: Porto Alegre,

Itanhaém, *Salino* 6624 (BHCB).

Distribution and habitat: Endemic to Brazil and Uruguay. This species is ecologically and geographically well characterized, and apparently is restricted to wet or seasonally inundated, grassy campos (coastal plains) dunes and “restinga” formations, at sea level along the coast from the State of São Paulo to Uruguay: São Paulo, Paraná, Santa Catarina, Rio Grande do Sul.

Deviates from *Lycopodiella longipes* by the generally shorter and wider, entire and often somewhat coriaceous leaves of the horizontal shoot, and in the erect axes by the appressed leaves and sporophylls, and narrow aspect of strobili.

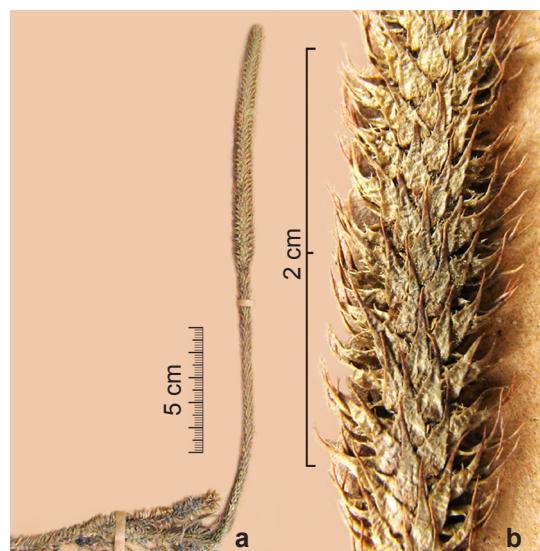

Figure 4 – *Lycopodiella tupiana*. Brazil, São Paulo, Peruibe, litoral sul do estado, Siegel 6 (HB). Holotype. – a. growth habit; b. part of strobilus with sporophylls.

Palhinhaea Vascon. & Franco, Bol. Soc. Broter. II, 41: 24. 1967. Type: *Palhinhaea cernua* (L.) Vasc. & Franco (=*Lycopodium cernuum* L.).

Lycopodiella sect. *Campylostachys* (K. Müller) B. Øllg., Opera Bot. 92: 175. 1987. - *Lycopodium* sect. *Campylostachys* K. Müller, Bot. Zeit. 19(24): 163. 1861. - *Lycopodium* subgen. *Rhopalostachya* Pritzel sect. *Cernua* Pritzel, Nat. Pflanzenfam. 1(4): 602. 1901, p.p. - Type: *Lycopodium cernuum* L.

Sporophytes with trailing to arching or looping indeterminate shoots which root with usually long intervals and occasionally branch in the horizontal plane, giving off horizontal branchlet systems, - and usually bearing one main erect branch arising on the dorsal side of every loop; the main erect branch bears a series of subdecussately arranged, spreading to hanging, flabellate branchlet systems, which in turn may terminate in sessile, nodding to pendulous strobili (*Palhinhaea bradei* is exceptional in lacking an erect aerial branch system, and in the erect, sessile strobili; *P.*

steyermarkii is unusual because of the long, slender, scandent, climbing, or creeping main axes, which give off spreading to flaccidly hanging lateral branchlet systems). Leaves and stem surfaces often with short, unicellular or pluricellular and branched hairs; sporangia almost enclosed in cavities formed by the strobilar cortex and the coalescent basal membranes of adjacent sporophylls (Figs. 7; 9; 10), subglobular, anisovalvate. The similar structure for *Lateristachys* Holub was described by Tardieu-Blot (1970). Sporangium epidermis cells with nodular or buttress-like, lignified thickenings on the side walls; spores rugate to nearly smooth; n = 104, 108, 110, 136, 156, c.165, 208.

Moist tropics, commonly pioneers on disturbed soil. *Palhinhaea cernua* is pantropical. Most other species have narrow distributions. 16–20 species in the Neotropics.

Species diversity is especially high on tropical mountains. *Palhinhaea steyermarkii* may grow as a high-climbing epiphyte. Species diversity seems higher in this group than commonly assumed.

Key to the species of *Palhinhaea* in Brazil

1. Plants with erect, tree-like branch systems, (rarely scandent or epiphytic), terminating in nodding to pendulous strobili; sporophyll margins denticulate to erose-denticulate.
 - 1'. Plants small, with creeping, mat-forming shoot systems; strobili ascending to erect, sporophyll margins smooth..... *Palhinhaea bradei*
 2. Branchlet leaves imbricate, distinctly flattened, lanceolate-ovate, with densely fimbriate margins
 - 2'. Branchlet leaves spreading to arcuate-appressed, acicular, terete, angular or apically flattened, smooth, or with more or less distant cilia or pointed hairs.
 3. Main stems slender, 1–1.5 mm thick, creeping or scandent, not forming robust erect, tree-like aerial shoots, with rather distant, loosely appressed leaves, glabrous; strobili to 9 cm long 3–4 mm thick, sporophylls 4–5 mm long..... *Palhinhaea steyermarkii*
 - 3'. Main stems robust, forming erect, tree-like aerial shoots, usually with crowded arcuate-ascending leaves, glabrous or hairy, strobili 2.5–3 mm thick, sporophylls 1–3 (–3.5) mm long.
 4. Lateral branchlet systems of dendroid erect branch usually stiffly ascending or suberect, often densely aggregated, ultimate branchlets pointing upward, not recurved; strobilus-bearing branchlets usually sharply reflexed at tip, or only the strobilus reflexed
 - 4'. Lateral branchlet systems of the dendroid erect branch patent to ascending, or recurved, the ultimate branchlets usually nodding, or long pendulous and sparsely branched distally.
 5. Ultimate branchlets divariccate to somewhat aggregate, patent to horizontal, usually with short-recurved tips; sporophyll margins coarsely erose-laciniate to irregularly dentate; slender to rather robust plants, usually with delicate to almost capillary leaves
 - 5'. Ultimate branchlets usually long pendulous, sparsely branched, almost parallel; sporophyll margins denticulate to dentate; relatively coarse plants with strongly curved, somewhat leathery leaves

- Palhinhaea cernua*
- Palhinhaea eichleri*

Palhinhaea bradei (Herter) Holub, Folia Geobot. Phytotax. 26: 93. 1991. Figs. 5; 6

Lycopodium bradei Herter, Revista Sudamer. Bot. 8: 21. 1949. - *Lycopodiella bradei* (Herter) B. Øllg., Opera Bot. 92: 176. 1987. - Type: Minas Gerais: Serra do Caparaó, Lajão, 2500 m, 18. 9. 1941, A.C. Brade 16959 (RB 45817; herb. Herter 61336 (?), AAU isotype).

Lycopodium fastigiatum R. Br. var. *schumacheri* Nessel, in Hoehne, Fl. Bras. Fasc. 11 (II:II): 119, fig. 106. 1955, *nom. nud.*

Plants prostrate, forming loosely appressed mats. Main stem to 25 cm long, rooting with short intervals, creeping, or sometimes underground, 1–2 mm thick excl. leaves, horizontally branched and giving off anisotomous, highly compound, flabellate, creeping to ascending, 2–6 cm long branchlet systems, which in turn may develop into new creeping main stems. Branchlets 3–6 mm diam. incl. leaves. Branchlet leaves usually borne in densely crowded, alternating low spirals or oblique whorls of 4–6, forming 8–12 obscure longitudinal ranks, 2–3.5 × 0.3–0.5 (–0.7) mm, acicular, flattened to terete or angular (dried), with often slightly acroskopically adnate, and long decurrent bases, arcuate-appressed to spreading, loosely to densely crowded, entirely glabrous. Strobili sessile, erect, terminating minor branchlets, 4–7 ×

2–2.5 mm excl. free sporophyll tips. Sporophylls borne in alternating whorls of 4–6, forming 8–12 longitudinal ranks, with coalescent leaf bases almost enclosing the sporangia, with triangular-lanceolate to widely triangular-ovate, short to long cuspidate, 1–1.5 × 0.5–0.8 mm, with usually strongly upward curved tip, entirely herbaceous, with smooth margins. Sporangia globose, ca. 0.7 mm diam.

Additional collections studied: BRAZIL MINAS GERAIS: Serra de Caparaó, 1800 m, Schwacke 6260 (RB). Campos do Caparaó, Schwacke (R 18292). Serra do Caparaó, trail to Pico da Bandeira, 41°45'W 20°30'S, 2400–2500 m, Windisch et al. 4962, 4967 (AAU, HB, SP). Caparaó, near Terreirão, 2400 m, Krieger CESJ 24224 (AAU). Alto Caparaó, trail Tronquera-base of Pico da Bandeira, region of Tres Lagoas, in trail to Pico do Cristal. 1800–2560 m, Salino et al. 11431 (photo in AAU ex BHCB). RIO DE JANEIRO: Itatiaia, Agulhas Negras, Campos Porto 1121 (AAU, RB). Itatiaia, Prateleiras, ca. 2200 m, Camerik 190, 191 (U).

Distribution and habitat: Endemic to SE Brazil. In addition to the type locality, *Palhinhaea bradei* is known from Mount Itatiaia, Agulhas Negras. Alt. 1800–2560 m. We have seen it on the type locality, where it grows on almost bare soil, with mosses, on the banks of the trail leading to Pico da Bandeira, at alt. 2300–2500 m (Fig. 6, habitat photo).

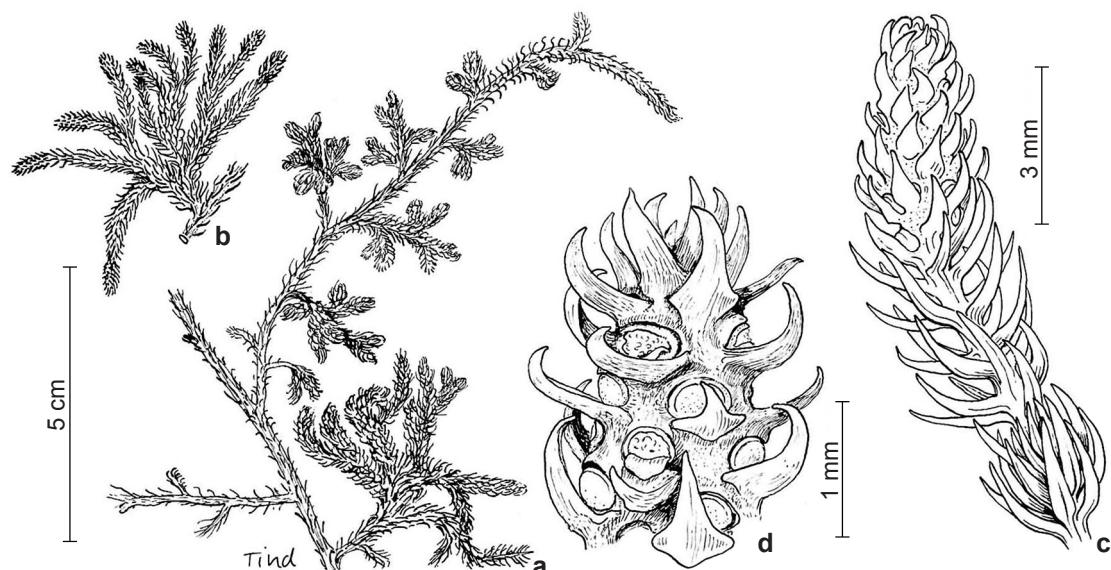

Figure 5 – *Palhinhaea bradei*. Brazil, Minas Gerais, Serra do Caparaó, Windisch et al. 4967 (AAU). – a. growth habit; b. fertile branchlet system; c. fertile branchlet; d. strobilus showing partly enclosed sporangia.

Figure 6 – *Palhinhaea bradei*. Brazil, Minas Gerais, Serra do Caparaó, Windisch et al. 4967 (AAU). Photo: B. Øllgaard.

This species is unique in *Palhinhaea* due to the absence of erect, tree-like aerial branch systems. The whole plant is prostrate, forming a flabellate shoot system. The main stems are creeping or occasionally underground. Also the erect strobili are unusual in the genus, in which the strobili are otherwise nodding or pendent. However, its coalescent sporophyll bases, almost enclosing the sporangia, the cell structure of the sporangium wall, and the spore morphology, clearly indicate that it belongs to *Palhinhaea*. The peculiar morphology made both Nessel and Herter (l. c.) consider it to be a dwarfed relative of *Lycopodium fastigiatum* (*Austrolycopodium*).

Palhinhaea camporum (B. Øllg. and Windisch) Holub, Folia Geobot. Phytotax. 26: 93. 1991.

Lycopodiella camporum B. Øllg. & P.G. Windisch, Bradea 5: 24, fig. 3. 1987. - Type: Brasil: Est. Minas Gerais: Mun. Santana do Riacho, estrada Lagoa Santa-Conceição do Mato Dentro, Km 113, Serra do Cipó, córrego do Vitalino, alt. 1150 m, campo rupestre, parte alta do barranco do córrego, inundada durante as cheias, 1 Feb. 1987, J. Prado et al. 69 (HB, holotype, AAU, RB, SP, SPF, isotypes).

Illustrations: Nessel (1927) tab. 43 and 44, as *Lycopodium cernuum* var. *eichleri*; Nessel (1955) fig. 110 in, as *Lycopodium cernuum* var. *eichleri*.

Plants with short to long, arching-looping runner shoots, rooting at soil contact, bearing stiffly erect, dorsally arising, amply branched, to 1 m tall, tree-like aerial shoots. Erect axes bearing several, subdecussate to alternate, often densely aggregated, stiffly ascending, 5–10 (–20) cm long lateral branchlet systems. Ultimate branchlets 2.5–7

mm diam. incl. leaves, stiffly ascending to erect, only the strobiliferous ones rather sharply recurved at the tip. Branchlet leaves usually borne in densely crowded, alternating low spirals or oblique whorls of 5–7, forming 10–14 longitudinal ranks, 2.5–4 × ca. 0.3–0.5 mm, acicular, terete or angular (dried), sometimes flattened in the lower half, with often slightly acroskopically adnate and long decurrent leaf bases, patently arcuate-ascending to arcuate-appressed, entirely smooth to densely hairy on leaf bases, rarely with soft hairs on leaf margins. Strobili usually numerous, sessile, terminating recurved tips of ultimate branchlets, to 2.5 cm long, 2–3 mm diam. Sporophylls borne in alternating whorls of 5–7, forming 10–14 longitudinal ranks, with coalescent leaf bases almost enclosing the sporangia, with widely ovate, short to long cuspidate, 1.5–2 × 0.6–0.9 mm, with scarious, coarsely erose-laciniate margins. Sporangia globose, ca. 0.6 mm diam., strongly anisovalvate.

Distribution and habitat: Amazonian Colombia, Peru, Bolivia, Argentina and Paraguay, savanna region of Venezuela, Guyana and Surinam. States of Roraima, Amazonas, Pará, Rondônia, Mato Grosso, Mato Grosso do Sul, Goiás, Distrito Federal, Bahia, Minas Gerais, São Paulo, Paraná. Swamps, moist campo-grasslands, on peaty or sandy soil, often in the light-open vegetation adjacent to gallery-vegetation at rivers, often subject to flooding during the rainy season; alt. 440–1800 m, most commonly 600–1200 m.

Palhinhaea camporum is a widespread species, which has been confused with *Palhinhaea pendulina*, *P. cernua* and synonyms thereof. The distinctive branching habit and characteristic ecology makes *P. camporum* a rather easily recognizable and biologically well-defined taxon, although detail characters do not seem strong. It is not rare to find the *P. cernua* and *P. camporum* growing together.

Plants with long arching-looping runner shoots, rooting at long intervals, bearing erect, dorsally arising, amply branched, to 1 m tall, tree-like shoots. Erect main axes bearing several, subdecussate to alternate, highly compound, spreading to horizontal, 5–15 (–20) cm long lateral branchlet systems. Ultimate branchlets nodding, 3–4 (–6) mm diam. incl. leaves. Branchlet leaves

usually borne in densely crowded, alternating whorls or low spirals of 3–5, forming 6–10 indistinct longitudinal ranks, usually 3–4 × ca. 0.3 mm, acicular, terete to angular (dried), with often conspicuously acroscopically adnate, and decurrent leaf bases, gradually changing from patent-reflexed and distant on main axes, to patent, upward curved and densely crowded in ultimate branchlets, occasionally with sparse, lax hairs or minute spinules; leaf bases often with longer, irregularly criped or branched hairs, these rarely also on stem surfaces. Strobili usually numerous, sessile, terminating ultimate branchlets, 4–10 (–20) × 2.5–3 mm. Sporophylls usually borne in alternating whorls of 5, forming 10 longitudinal ranks, with coalescent leaf-bases almost enclosing the sporangia, with ovate-deltoid, short to long cuspidate, ca. 2 mm long, ca. 1 mm wide exterior face, with membranous, coarsely erose-laciniate margins. Sporangia globose, 0.5–0.8 mm diam., strongly anisovalvate, the epidermis cells with straight, unlignified side walls and buttress-like lignified thickenings. Spores rugate, without a distinct equatorial rim.

Distribution and habitat: Pantropic. Probably present in all the states of Brazil. A common pioneer species throughout the humid regions of the country, on road cuts and moist disturbed soil, along rivers, in forest clearings etc., from sea level to 2200 m alt.

A variable taxon. Nessel (1927, 1955), recognized a number of varieties, but we are unable

to apply these. When *Palhinhaea cernua* grows in open, exposed habitats it has the typical growth habit with stiffly erect, tree-like aerial shoots; however, in shaded, moist habitats the aerial shoots may branch profusely, and may grow to more than 2 m long, becoming gradually overhanging or subscendent.

***Palhinhaea eichleri* (Fée) Holub, Fol. Geobot. Phytotax. 20: 78. 1985.** Fig. 8

Lycopodium eichleri Fée, Crypt. Vasc. Brésil II: 96, t. 106, f. 4. 1872–1873. - *Lycopodium cernuum* L. var. *eichleri* (Fée) Nessel, Arch. Bot. Est. S. Paulo 1: 446. 1927. - *Lycopodiella eichleri* (Fée) B. Øllg., Opera Bot. 92: 176. 1987. - Type: Brasilia fluminensi, Alto-Macahe, 1600 m, *Glaziou* 4478 (P! holotype, C! isotypes).

Illustrations: Nessel in Hoehne, Fl. Bras. fasc. 11 (II:II): fig. 111. 1955, as *Lycopodium cernuum* var. *eichleri*.

Dendroid branch systems to ca. 40 cm tall, amply branched, with sparsely to profusely subequally branched, to 12 (–20) cm long, usually long pendulous lateral branchlet systems. Leaves of main axes loosely appressed, upward curved, 5–7 × 0.5–1 mm. Ultimate branchlets (3–) 5–6 (–9) mm diam. incl. leaves, rarely tapering to 2 mm diam. Branchlet leaves borne in densely crowded alternating whorls or low spirals of 5–7, forming 10–14 indistinct longitudinal ranks, acicular, terete to quadrangular (dried), or sometimes apically flattened, (3–) 4–6 × 0.5–1 mm, patent-ascending, upward curved, softly to firmly herbaceous, glabrous, or with few marginal cilia. Leaf bases and stem surfaces usually with sparse to dense short crisped hairs. Strobili 10–20 × 5–6 mm. Sporophylls borne in alternating whorls of 5–6, forming 10–12 longitudinal ranks, (2.5–) 3–3.5 × ca. 1.5 mm, with lanceolate-ovate, short acuminate exterior face, with irregularly dentate, very narrowly membranous margins, greenish, of herbaceous texture throughout. Sporangia ca. 1 mm diam.

Collections studied: BRAZIL. MINAS GERAIS: Ouro Preto, road to Cachoeira das Andorinhas, alt. 1300 m, *Windisch et al.* 4959A, 4960 (AAU). Serra de Ouro Preto, *Damazio* 1149 (P). Lima Duarte, Parque Estadual Ibitipoca, trail to Janela do Céu, *Almeida et al.* 1227 (BHCB). RIO DE JANEIRO: Alto Macahé, alt. 1600 m, *Glaziou* 4478 (C, P). Itaipava-Teresópolis, alt. 900 m, *Pabst et al.* 7148 (GH, HB, M, VEN). Serra do Mar, access road to Serra da Bocaina, *Windisch et al.* 5009 (AAU, HB, SP). “Sommet du Tinguá, au plus haut pic”, *Glaziou* 9067 (P).

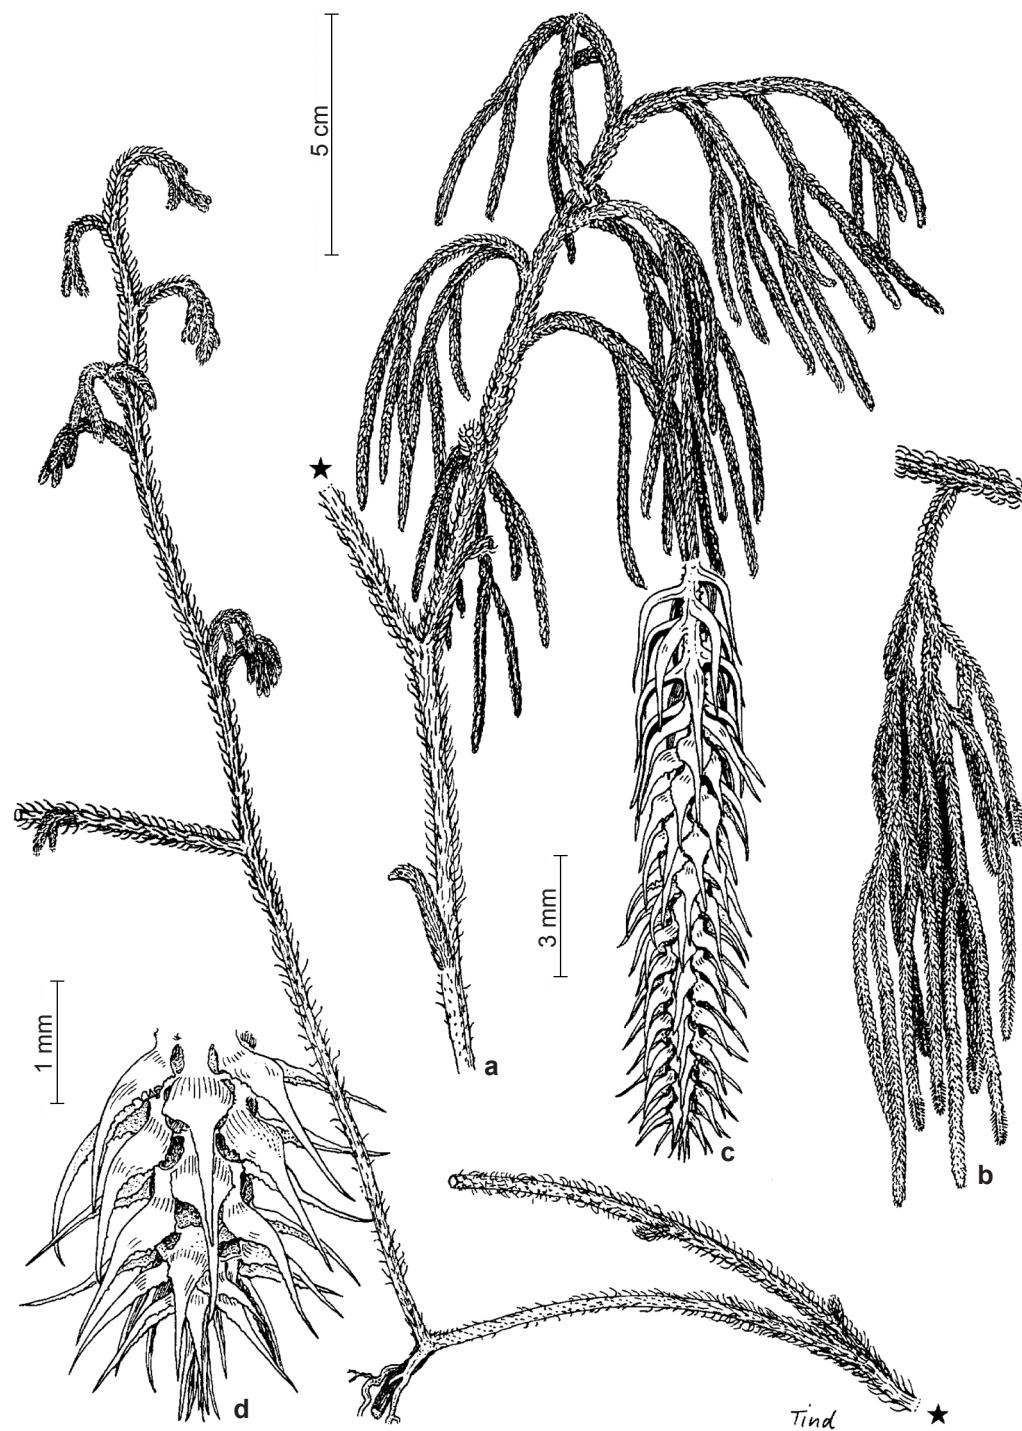

Figure 8 – *Palhinhaea eichleri*. Brazil, São Paulo, Serra do Mar, Cunha-Paraty, Windisch et al. 5009 (AAU). – a. growth habit; b. branchlet system; c. strobilus; d. strobilus, enlarged.

Distribution and habitat: Brazil: States of Minas Gerais, Rio de Janeiro. Open sites in cloud forest, alt. 900–1600 m.

Nessel's illustrations (1927, tab. 43–44; 1955, fig. 110) indicated to be *Lycopodium cernuum* var. *eichleri* and var. "pendulum" Hook." respectively, are of *Palhinhaea camporum*, and not the present species.

Palhinhaea eichleri is possibly related to *P. pendulina* (Hook.) B. Øllg. (Costa Rica to northern Andes), to which it was referred by Øllgaard & Windisch (1987). However, it differs in the ultimate hanging branchlets being slender and tapering, and the stem surfaces and leaf bases densely hairy. The material from the vicinity of Ouro Preto seems to represent a slender form of the species. We have seen *P. eichleri* growing together with *P. cernua* on open road banks in Serra da Bocaina. The differences of growth habit and general dimensions are obvious under such circumstances. However we have also seen numerous intermediate individuals and undecisive with respect to their possible hybrid origin. The intermediate individuals appear to have normally developed spores.

Palhinhaea riofrioi (Sodiro) Holub, Fol. Geobot. Phytotax. 26: 93. 1991. Fig. 7g-i

Lycopodium riofrioi Sodiro, Anal. Univ. Quito 12: 395 (1895) [Crypt. vasc. quitens. 582 (1893)]. - *Lycopodiella riofrioi* (Sodiro) B. Øllg., Opera Bot. 92: 176 (1987). - Type: Ecuador, In silv. occid. m. Pichincha ad Gualea, 9/888, Sodiro s.n. (SI 21230 holotype!).

Lycopodium pensum Lellinger & Mickel ex Lellinger, Proc. Biol. Soc. Washington 89: 717, fig. 2 (1977). - Type: Costa Rica, prov. Heredia, 6 mi. from San Rafael de Heredia on slopes of Volcán Barba (Cerro Chompipe), McAlpin 216 (DUKE holotype n.v.; GH isotype!).

Illustrations: Lellinger, Proc. Biol. Soc. Washington 89: 717, fig. 2 (1977) as *Lycopodium pensum*.

Plants with very short to long, arching-looping runner shoots, rooting at soil contact, these bearing dorsally arising, erect, to 2 m tall, tree-like branched shoots. Erect shoots with several subdecussate to alternate, 10–25 cm long, subequally branched, ultimately long pendulous lateral branchlet systems. Ultimate branchlets 2–3 mm diam. incl. leaves. Branchlet leaves imbricate, densely crowded, borne in alternating whorls of 4–6, these 1–1.5 mm apart, forming 8–12 longitudinal ranks, lanceolate to ovate-lanceolate, acuminate, 2.5–4 × ca. 1 mm

wide, with densely ciliate-fimbriate margins, with a very short, patent, terete-subangular base. Stems and leaf bases densely hairy. Strobili sessile, terminating ultimate branchlets, 10–25 × 3–5 mm diam. incl. sporophylls. Sporophylls borne in alternating whorls of 5, forming 10 longitudinal ranks, with coalescent bases, almost enclosing the sporangia, ca. 2.5 × ca. 1 mm, with deltoid, short acuminate exterior face, with narrowly membranous, erose-laciniate margins. Sporangia 0.7–1 mm diam. Spores rugate, without a distinct equatorial rim.

Collections studied: BRAZIL. AMAZONAS: Santa Isabel do Rio Negro, 0°00'N 65°00'W, P.N. do Pico da Neblina, trail to Anta waterfall, between camp Lajero and Marco 5 of frontier Brazil/Venezuela, cloud forest ascending to Serra da Neblina, Carvalho et al. 370 (INPA). RORAIMA: Frontier between Territory Rio Branco, Brazil, and Estado Bolívar, Venezuela, Serra do Sol, alt. 2100 m, Maguire 40399 (COL, F p.p., NY; - the other part the collection at F may be a hybrid with *Palhinhaea cernua*).

Distribution: Costa Rica, Panama, Venezuela and adjacent Brazil, Colombia, Ecuador.

The putative hybrid *Palhinhaea cernua* x *rioifrioi* is known from Cerro Neblina (e.g., Beitel 85194, AAU), the Chimantá Massif (Steyermark & Wurdack 842, AAU, VEN), Meseta de Jaua (Steyermark et al. 109548, US, VEN), Auyan-tepui (Cardona 2645, US, VEN), and Mount Roraima (Steyermark 58935, F, US). Also in Panama. It is distinguished from both of its parents by more vigorous growth. The leaves are wider, coarser and more hairy than in *P. cernua*, and the leaves of the main axes are usually appressed, and all axes more hairy.

Palhinhaea steyermarkii (B. Øllg.) Holub, Fol. Geobot. Phytotax. 26: 93 (1991). Fig. 9

Lycopodiella steyermarkii B. Øllg., in Harling & Andersson, Fl. Ecuador 33: 149 (1988). - Type: Ecuador: Prov. Napo: Road Baeza-Tena, ca. Km 23, ca. 2000 m, Øllgaard et al. 35959 (AAU holotype, QCA isotype).

Illustrations: Nessel's illustration (Bärlappgewächse 313, Abb. 72. 1939) of *Lycopodium sprucei* Baker is *Palhinhaea steyermarkii*, shown upside down.

Plants with long, slender, scandent, climbing, or creeping main axes, which give off lateral branchlet systems of spreading to flaccidly hanging, at least to 30 cm long branchlets. Main axes 1–1.5 mm thick excl. leaves, glabrous. Ultimate branchlets incl. leaves 4–5 mm diam. Leaves of main axes distant, borne in drawn-out spirals or very irregular

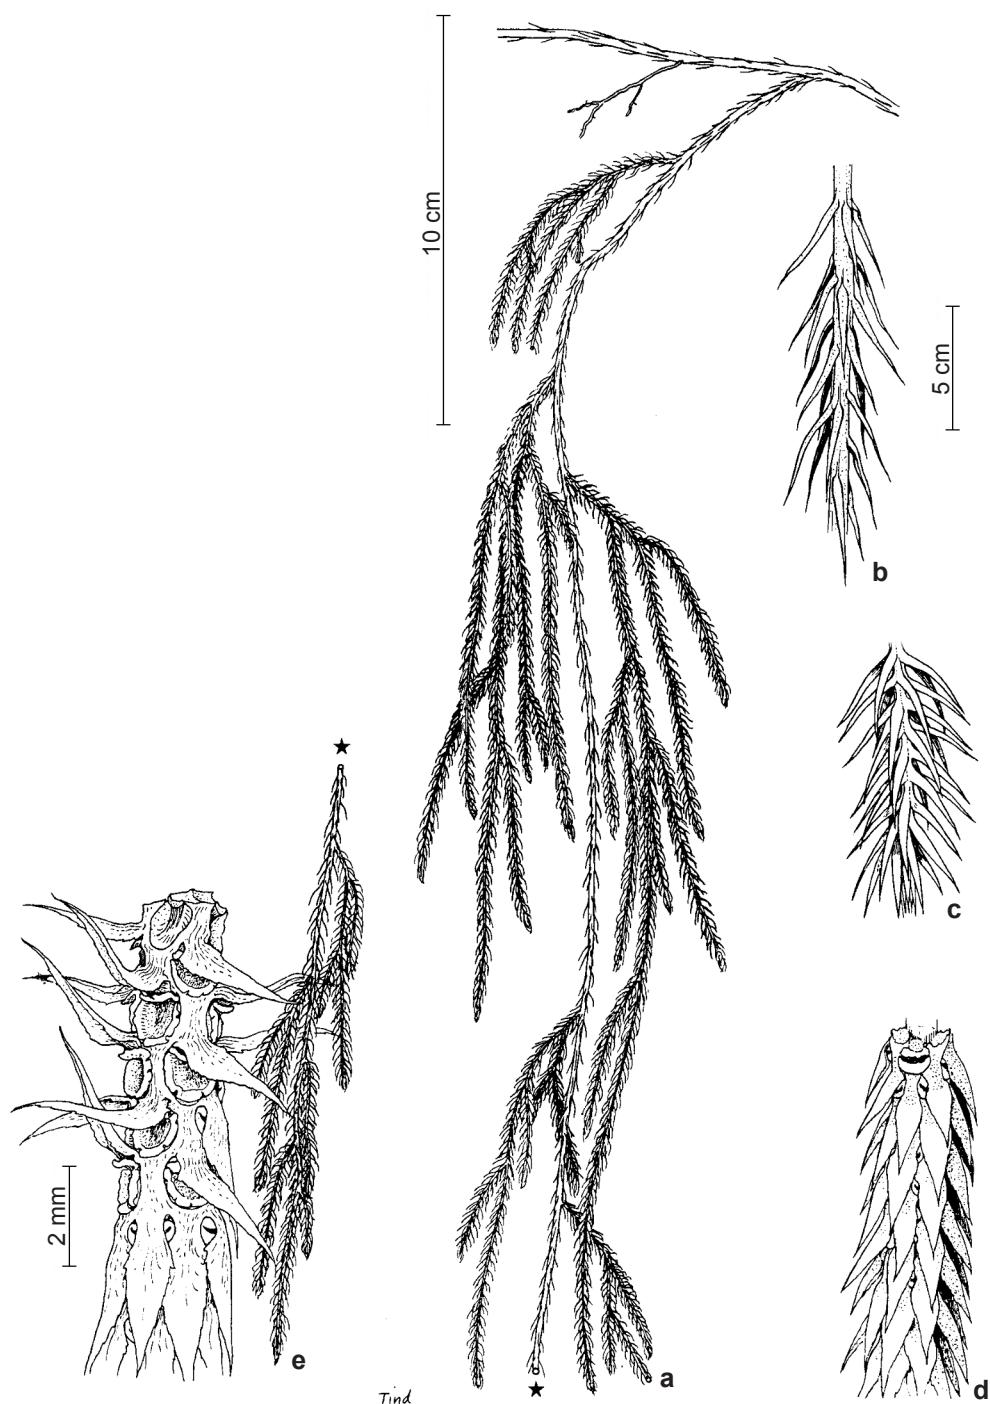

Figure 9 – *Palhinhaea steyermarkii*. Ecuador, Øllgaard *et al.* 35959 (AAU). – a. growth habit; b. major branchlet; c. terminal branchlet; d. part of strobilus; e. part of strobilus showing partly enclosed sporangia.

whorls, 8–12 seriate, acicular, semiterete to flattened, soft, with a long, slender tip, arcuate-ascending to appressed, 4–6 mm long, glabrous. Branchlet leaves softly to firmly herbaceous, arcuate-ascending to arcuate-appressed, 3–5 × ca. 0.5 mm, evenly tapering from the base, otherwise conform. Strobili to 9 cm long, ca. 4 mm thick (with appressed sporophylls). Sporophylls borne in alternating whorls of 4, forming 8 longitudinal ranks, with coalescent sporophyll bases almost enclosing the sporangia, with lanceolate to lanceolate-ovate, 4–5 × 1–1.5 mm, with shallowly erose-denticulate margins, of herbaceous, green texture throughout. Sporangia globose, 1–1.2 mm diam.

Collections studied: BRAZIL. RORAIMA: Roraima, am Felsenabhang, Dec 1909, 2300 m, Ule 8496 (BONN-Nessel 201, K, L, Museo Goeldi photo). Roraima, Ule 8416 (BONN-Nessel 200).

Distribution and habitat: Panama, Venezuelan Guayana, Guyana-Venezuela border, Colombia, Ecuador. In Brazil this species is known only from the State of Roraima. Terrestrial or epiphytic in pluvial montane forest, 1900–2200 m. Guayana: Terrestrial, scrambling or creeping, with pendent branchlets, on shaded stream banks, sandstone escarpments, and moist bluffs, 1600–2300 m.

This is the only species in the genus known to grow as an epiphyte. In Venezuela it is mainly terrestrial.

The strobili are remarkably long for this section of the genus. They apparently remain meristematically active for a prolonged period, often having wilted and rotten sporophylls and sporangia at the strobilus base, and at the same time a fresh, actively developing strobilus apex

Pseudolycopodiella Holub, Folia Geobot. Phytotax. 18: 441. 1983. - Type: *Pseudolycopodiella caroliniana* (L.) Holub (= *Lycopodium carolinianum* L.).

Lycopodium sect. *Caroliniana* Bruce, Amer. Fern J. 66: 136. 1976. - *Lycopodiella* sect. *Caroliniana* (Bruce) B. Øllg., Opera Bot. 92: 174. 1987. - Type: *Lycopodium carolinianum* L.

Sporophytes with prostrate, rooting, indeterminate, isophyllous to strongly anisophyllous, horizontally branching shoots, and dorsally arising, erect, simple strobiliferous branches; leaves of strobiliferous branches conform to leaves of prostrate shoots or strongly reduced and distant; sporophylls arranged in alternating whorls of 3–5, rarely decussate, forming 4–10 (–12) longitudinal ranks, free, not enclosing the sporangia at maturity, without veinal mucilage canals; sporangia isovalvate, reniform, widely attached to the sporophyll stalk: sporangium epidermis cells with incompletely lignified or incompletely semiannular thickenings; n = 35, 70, 2n = 115 (Bruce 1976c), n = 68 (Takamiya & Kurita 1983), n = c. 69 (Walker 1966).

Tropical and temperate regions, western temperate Asia, Australia, and western temperate North America, absent from Europe. Most species grow on moist or boggy, sandy soil. Some species are adapted to seasonal drought and fire, and may survive such periods by means of subterranean, tuberous stem apices (Kornas 1975). Four to ten rather poorly understood species, with the highest diversity and the primitive, isophyllous species in South America and Australia to New Caledonia (*Pseudolycopodiella serpentina*). A thick spongy cortex in the prostrate shoots seems to have developed independently as an adaptation to marshy or shallowly inundated growth conditions in species in Southern Africa, Brazil and the Guiana Highlands. Ballard (1950) studied the variability of the African species. Bruce (1976c) gave a detailed account of the morphology of the type species.

Key to the species of *Pseudolycopodiella* in Brazil

1. Creeping shoots anisophyllous
2. Creeping stems terete, not fleshy or spongy; the upper side not wide or flattened, dorsal leaves closely spaced
 3. Creeping shoots more than 7 mm wide, with lanceolate to subulate, 3–7 mm long lateral leaves; dorsal leaves widely lanceolate to subulate *Pseudolycopodiella meridionalis*
 - 3'. Creeping shoots to 6 (–7) mm wide, with dimidiate to triangular-ovate or widely lanceolate, 2–3 mm long lateral leaves; dorsal leaves widely ovate to ovate-acuminate *Pseudolycopodiella paradoxa*
- 2'. Creeping stems fleshy or spongy, the upper side wide and flattened

4. Dorsal leaves with approximate, clearly delimited leaf bases, scale-like, covering the dorsal side of the stem.....*Pseudolycopodiella squamata*
- 4'. Dorsal leaves with distant leaf bases, the stem surface much exposed, narrow leaves rarely present on ventral side of the stem.....*Pseudolycopodiella carnosa*
- 1'. Creeping shoots entirely isophyllous
5. Creeping stems fleshy and spongy, the upper side somewhat flattened.....
-*Pseudolycopodiella tatei*
- 5'. Creeping stems terete, not fleshy or spongy
6. Vegetative leaves of erect, strobiliferous branch densely crowded, strongly upward curved from an almost perpendicular, terete to angular leaf base; strobiliferous branch incl. leaves appearing as thick as, or thicker than the strobilus*Pseudolycopodiella contexta*
- 6'. Vegetative leaves of strobiliferous branch distant or subdistant, their bases flattened and appressed, often with slightly recurved tips; strobili appearing thicker than vegetative strobiliferous branch incl. leaves.....*Pseudolycopodiella iuliformis*

Paulo 1: 432. 1927. - *Pseudolycopodiella goyazensis* (Underw. & Lloyd) Holub, Folia Geobot. Phytotax. 18: 442. 1983. - Type: Brazil: Goyaz: Glaziou 22644 (NY holotype; P, isotypes).

Terrestrial, with short, fleshy, horizontal stems creeping and firmly rooted throughout, bearing one to few, dorsally arising, stiffly erect, simple, strobilus-bearing branches (peduncles). Creeping shoots to ca. 20 cm long, sparsely and unequally branched, 7–15 mm wide incl. leaves, strongly anisophyllous, with large and wide lateral leaves, and short, narrow and often rudimentary dorsal leaves, the fleshy, more or less naked-appearing stem surface 2–5 mm wide excl. lateral leaves. Lateral leaves 3–8 × 1.5–3.5 mm, usually widely triangular-lanceolate and

somewhat falcately recurved, flat, with smooth, underlying acroscopic margins and short to long decurrent basiscopic margins, varying from widely triangular to linear-lanceolate (sometimes in the same individual); dorsal leaves relatively distant, arranged in 1–3 (–4) longitudinal ranks (often on the same individual), awl-shaped to subulate, or rarely ovate-acuminate, often rudimentary, appressed to reflexed from a diverging to almost perpendicular base, 1–2 (–3) × ca. 1 (–1.5) mm. Peduncle to 40 cm tall incl. the strobilus, 1–2 mm thick excl. leaves, terete, bearing small (ca 3–5 mm long) subulate leaves in remote, alternating, irregular whorls of 4–6. Strobili to 15 cm long, ca. 4–8 mm thick with appressed sporophylls, ca. 8–12 mm thick including spreading sporophylls. Sporophylls borne in alternating whorls of 4–6, forming 8–12 longitudinal ranks, subpeltate, with a thin, median, basiscopic, decurrent wing on the stalk, with a widely ovate-rhombic to widely lanceolate, acuminate, exterior face, 4–7 × ca. 2–2.5 mm, with minutely fimbriate-denticulate margins. Sporangia reniform, isovalvate, borne on the sporophyll stalk, ca. 1.5–2 mm wide.

Distribution and habitat: Paraguay, Bolivia. In Brasil: States of Bahia, Goiás, Mato Grosso, Mato Grosso do Sul, Distrito Federal, Minas Gerais, São Paulo, Paraná, Santa Catarina, Rio Grande do Sul. Terrestrial, usually on wet or humid grasslands and swampy areas, on road banks, slopes, ledges, grasslands, dunes, "restinga" formations, alt. sea level to ca. 1300 m frequently on bare soil covered by blue-green algae.

Pseudolycopodiella carnosa is easily recognized by the characteristic bare, fleshy creeping stems. The stems are very brittle, densely and firmly attached to the soil, so most herbarium collections are somewhat fragmented.

Pseudolycopodiella sarcocaulon (Kuhn) Holub (= *Lycopodium carolinianum* L. var. *grandifolium* Spring) from Southern Africa is very similar to *P. carnosa* with respect to the fleshy

stems and either is a close relative or a similar adaptation.

Pseudolycopodiella contexta (Mart.) Holub, *Folia Geobot. Phytotax.* 26: 93. 1991. Fig. 11e-h

Lycopodium contextum Martius, *Icon. Crypt. Brasil.* 38, t. 20, f. 1. 1834. - *Lycopodium alopecuroides* L. var. *contextum* (Martius) Baker, *Handb. Lycopodium sprucei Baker, *Handb. Fern Allies* 24. 1887. - Type: Venezuela, San Carlos del Rio Negro, *Spruce* 3151 (holotype, K!; isotype, BONN, frag. Herb. Nessel 200! p.p.).

Horizontal shoots closely appressed to the ground, to at least 30 cm long, rooted with short intervals, sparsely branched in the horizontal plane, bearing stiffly erect, dorsally arising, simple, or sometimes 1–2 times forked, to at least 40 cm tall, vegetative or strobiliferous aerial shoots. Horizontal shoots densely covered on all sides by uniform leaves, 3–7 mm in diam incl. leaves, stems excl. leaves 1–2.5 mm thick. Leaves of horizontal shoots uniform, somewhat upward secund, ascending, acicular. Aerial shoots 4–6 mm diam. incl. leaves, densely foliose, with radially arranged, uniform leaves. Leaves of aerial shoots borne in alternating low spirals or irregular whorls of 6–7, 0.8–1.5 (–2) mm apart, forming 12–14 indistinct longitudinal ranks, terete at the base (or angular when dried), upward sometimes flattened, strongly upward curved from a strongly diverging to almost perpendicular base, 4–5 (–7) × ca. 0.5 mm, with conspicuously acroskopically adnate and long decurrent leaf bases, with smooth margins. Strobili to 8 cm × 3–4 mm diam. with appressed sporophylls, to 12 mm diam. with distended sporophylls. Sporophylls borne in alternating whorls of 4–5, forming 8–10 longitudinal ranks, subpeltate, with a basispic, compressed membranous wing on the stalk, the exterior face with widely triangular-ovate to ovate-lanceolate base and a long, narrow apex, 4.5–7 × 1–1.5 mm, with subentire to slightly erose-dentate margins at the base. Sporangia borne on the sporophyll base, reniform, isovalvate, 1–1.5 mm wide.

Collections studied: BRAZIL ACRE: Cruzeiro do Sul, *Marinho* 76 (NY). Cruzeiro do Sul, near new airport, *Monteiro & Damião* 254 (INPA). AMAZONAS: Alto Rio Negro, Cucui, Serra de Tunui, *Calvante* 3057 (INPA, NY). On slope of Serra Aracá, *Rosa & Lira* 2374 (NY). Cucurú, Rio Ayarí, *Luetzelburg* 22777 (R). Rio Cariua (Igarapé Branco) from Rio Curicuriari to Cachoeira de Bôto (C. Piraiuara), *Poole* 2009 (NY, US). Intica, Rio Uaupés, *Luetzelburg* 23041(R), 23614 (M, R, UC). PARÁ: Rio Cururu Açu, *Sick* B-703 (HB). RONDÔNIA: Mutum Cavallo (Juruena-C. Novo), *Hoehne* 5372, 5373 (R).

Distribution and habitat: Circum-Amazonian, Amazonian lowland of Peru, Colombia and Venezuela. Brazil: Acre, Amazonas, Pará, Rondônia. Habitat: Terrestrial, humid places on white sand, grasslands and river margins, alt. 120–1750 m.

***Pseudolycopodiella iuliformis* (Underw. & Lloyd)**
Holub, Folia Geobot. Phytotax. 18: 442. 1983.

Fig. 11a-d

Lycopodium iuliforme Underw. & Lloyd, Bull. Torrey Bot. Club 33: 120. 1906. - *Lycopodiella iuliformis* (Underw. & Lloyd) B. Øllg., Opera Bot. 92: 176. 1987. - Type: Venezuela: Summit of Roraima, 8,600 ft. *McConnel & Quelch* 572 (NY holotype).

Horizontal shoots closely appressed to the ground, at least to 20 cm long, rooted with short intervals, sparsely to densely branching in the horizontal plane, sometimes forming small mats, bearing stiffly erect, dorsally arising, simple, at least to 30 cm tall strobiliferous branches. Horizontal shoots densely covered on all sides by leaves, 7–10 mm diam. incl. leaves. Stems excl. leaves 1–3 mm thick. Leaves of horizontal shoots uniform, usually upward secund and curved, acicular, flattened with a subterete to compressed leaf base (angular when dried), or sometimes terete or angular throughout, 4–6 × 0.5–0.8 (–1) mm, with smooth margins. Leaf bases not, or only slightly acroskopically adnate, short to long decurrent. Erect strobiliferous shoots 3–4 mm diam. incl leaves, 1.5–2 mm excl. leaves, with uniform, radially arranged leaves. Vegetative leaves of erect shoots borne in alternating, irregular whorls of 4–6, 2–4 mm apart, forming 8–12 obscure longitudinal ranks, appressed throughout, flattened, subulate, ca. 5 × ca. 0.8 mm, evenly tapering. Strobili at least to 11 cm long, 4–5 mm diam. with appressed sporophylls, to 14 mm in diam with distended sporophylls. Sporophylls borne in alternating whorls of 5–6, forming 10–12 longitudinal ranks, subpeltate, with a basiscopic, compressed membranaceous wing on the stalk, the exterior face with a widely ovate to

rhombic basal part and an abruptly to evenly tapering, long apex, 5–8 × 1.5–2 mm, with finely erose-dentate margins. Sporangia borne on the sporophyll base, reniform, isovalvate, 1.5–2 mm wide.

Collections studied: BRAZIL AMAZONAS: Ridge line on Venezuela-Brazil border, Cerro Neblina, 1900–2100 m, *Gentry & Stein* 46731 (AAU, MO). São Gabriel da Cachoeira, Alto da Serra da Neblina, *Carvalho et al.* 378 (BHCB). RORAIMA: Monte Roraima, *Viana et al.* 33464 (BHCB).

The description above covers only the Brazilian material. *Pseudolycopodiella iuliformis* is a highly variable species, confined to the Guyana Highlands. Brazil: Amazonas and Roraima.

***Pseudolycopodiella meridionalis* (Underw. & Lloyd)**
Holub, Folia Geobot. Phytotax. 18: 442. 1983.

Fig. 10d-f

Lycopodium meridionale Underw. & Lloyd, Bull. Torr. Bot. Club 33: 121. 1906. - *Lycopodium carolinianum* L. var. *meridionale* Nessel, Arch. Bot. Est. S. Paulo 1: 431. 1927. - *Lycopodiella caroliniana* (L.) Pichi-Sermolli var. *meridionalis* (Underw. & Lloyd) B. Øllg. & Windisch, Bradea 5: 27. 1987. - Type: Puerto Rico: Dry savannahs, Luquillo Mountains, *Percy Wilson* 94 (NY! holotype, US, isotype).

Terrestrial, with horizontal stems creeping and firmly rooted throughout, bearing one to few, dorsally arising, stiffly erect, simple, strobilus-bearing branches (peduncles). Creeping shoots to ca. 30 cm long, sparsely and unequally branched, 7–12 (–15) mm wide incl. leaves, 1–2 mm thick excl. leaves, anisophyllous, with long and wide lateral leaves, and usually shorter and narrower dorsal leaves; lateral leaves 3–5 (–7) × (1–) 1.5–2.5 (–3) mm, varying from widely triangular-ovate to lanceolate (sometimes in the same individual), obliquely spreading to falcately recurved, usually with a strongly curved, underlying acrosopic margin, and short to long decurrent basiscopic margins, tapering into an acute to long pointed apex, flat, with smooth margins. Dorsal leaves arranged in (1–) 2–4 longitudinal ranks (often on the same individual), widely lanceolate to subulate (rarely triangular-ovate), diverging to appressed, straight to upward curved, (1.5–) 3–4 (–5) × 1–1.3 (–2) mm. Erect branches at least to 30 cm tall incl. the strobilus, 1–1.5 mm thick excl. leaves, terete, bearing small, 3–5 mm long, acicular leaves in remote, alternating spirals or irregular whorls of 4–5, these 4–8 mm apart. Strobili to at least 13 cm long, 3–5 mm thick with appressed sporophylls, 8–10 (–12) mm diam. incl. spreading sporophyll

tips. Sporophylls borne in alternating whorls of 4 or 5 (–6), forming 8–10 (–12) longitudinal ranks, subpeltate, with a thin, median, basiscopic, decurrent wing; the exterior face rhombic or ovate-acuminate or ovate-cuspidate to triangular-lanceolate, 3.5–6 × (1–) 1.5–2 (–2.5) mm, with subscarious, entire to erose-denticulate, minutely fimbriate-denticulate margins. Sporangia reniform, isovalvate, ca. 1.5–2 mm wide.

Distribution and habitat: Widely distributed in tropical America, but rare in the Andes. Ecuador, Peru and Venezuela, south to Argentina (Concepción). Brasil: states of Roraima, Amapá, Amazonas, Maranhão, Piauí, Pernambuco, Bahia, Goiás, Minas Gerais, Rio de Janeiro, São Paulo, Paraná, Santa Catarina, Rio Grande do Sul. Terrestrial or sometimes epilithic, usually on moist or wet ground, on road banks, slopes, ledges, grasslands, dunes, restinga, alt. sea level to ca. 1300 m.

***Pseudolycopodiella paradoxa* (Mart.) Holub, Folia Geobot. Phytotax.** 18: 442. 1983.

Fig. 10a-c

Lycopodium paradoxum Mart., Icon. Pl. Crypt. Brasil., 38, t. 20, f. 2. 1838. - *Lycopodium carolinianum* L. var. *paradoxum* (Mart.) Christ, in Schwacke, Pl. Nov. Mineiras 2: 42. 1900. - *Lycopodium carolinianum* L. subsp. *paradoxum* (Mart.) Hassler, Trab. Inst. Farm. Buenos Aires 45: 93. 1928. - *Lycopodiella caroliniana* (L.) Pichi Sermolli var. *paradoxa* (Mart.) B. Øllg. & Wind., Bradea 5: 27. 1987. - Type: Crescit in Brasiliae prov. Sebastianopolis in sylvis montanis, 1817, Martius, Iter Brasiliense (M, holotype).

Lycopodium carolinianum L. var. *springii* Christ, Denkschr. Kaiserl. Akad. Wiss., Mat.-Nat. Kl. 79: 59. 1908. - Type: Rio Grande, São Paulo Railway, *Wettstein & Schiffner* s.n. (W not seen, P herb. Christ, BONN, herb. Nessel).

Creeping shoots 3–6 (–7) mm wide incl. leaves. Stem 1 mm or less thick excl. lateral leaves. Lateral leaves 2–3 (–3.5) × 1.5–2 (–2.5) mm, usually widely obliquely triangular-ovate or widely

lanceolate to almost dimidiate, somewhat falcately recurved, with a strongly convex acroscopic margin, acute to subobtuse. Dorsal leaves usually close and imbricate, arranged in 1–3 longitudinal ranks (often on the same individual), widely ovate to ovate-acuminate, 1–2 × ca. 0.8–1.5 mm. Erect branches to 10 (–13) cm tall incl. the strobilus, 1 mm or less thick excl. leaves, bearing small (ca. 2–3 mm long) subulate leaves in remote, alternating, irregular whorls of 3–4 (–5). Strobili to 6 cm long, ca. 2.5–3.5 mm thick with appressed sporophylls, ca. 5–7 mm thick including spreading sporophylls. Sporophylls borne in alternating whorls of 3–4 (–5), forming 6–8 (–10) longitudinal ranks, with a widely rhombic-ovate or triangular-ovate, acuminate to long-cuspidate exterior face, 3–4 (–5) × ca. 1.5–2.5 mm, with minutely fimbriate-denticulate margins. Sporangia ca. 1.5 mm wide.

Campo Novo, Mafra, 800 m, *Reitz & Klein* 4860 (HBR, US).

Distribution and habitat: Roraima sandstone formation of Venezuela, savanna region of Colombia, Paraguay, and the Brazilian Planalto. Open, wet localities on sandy soil, river margins,

700–1750 m alt., in the states of Acre, Mato Grosso, Mato Grosso do Sul, Goiás, Distrito Federal (Brasília), Minas Gerais, São Paulo, Paraná, Santa Catarina. Habitat: Open, wet localities on sandy soil, river margins, 700–1750 m alt.

Similar to *Pseudolycopodiella meridionalis* in most features, but differs in the much smaller average size, and the proportions of the lateral and dorsal leaves.

Some specimens, e.g. *Windisch* 5380, and 5943 from Mato Grosso, seem intermediate to *P. meridionalis*, due to a more elongate growth habit.

***Pseudolycopodiella squamata* B. Øllgaard & P.G. Windisch, sp. nov.**

Fig. 12

Diagnosis: Species nova *Pseudolycopodiella tatei* et *P. carnosae* affinis a quibus differt foliis dorsalibus caulis horizontalis valde adnatis squamiformibus, marginibus decurrentibus foliorum basium distincte marcatis.

Type: Brazil, estado de Mato Grosso, mun. Cuiabá, Complexo da Chapada dos Guimaraes, caminho de acesso ao Véu da Noiva. Campo. Local húmido con afloramento de água. Terrestre, verde oscuro (mais opaco que *L. carnosa*), folhas adpressas, crescendo junto com 5378 (*L. carnosa*) e por vezes entremeada com a mesma, ca. 550 m alt. 25.I.1989, P.G. *Windisch* 5379 (AAU, holotype; HB, isotype)

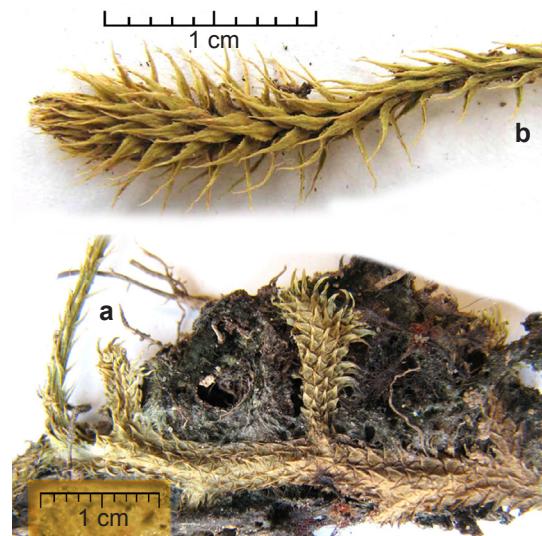

Figure 12 – *Pseudolycopodiella squamata*. Brazil, Mato Grosso, Chapada dos Guimaraes, *Windisch* 5379 (AAU). – a. prostrate stems; b. strobilus.

Horizontal shoots creeping, the stem flattened and fleshy, firmly rooted, sparsely irregularly ramified, to 15 cm long, 7–12 (–20) mm wide incl. leaves, anisophyllous, with the lateral leaves long, the dorsal leaves shorter with widened, contiguous bases, covering the stem surface completely. Lateral leaves 2–5 (–7) × 0.8–2 (–2.5) mm, narrowly triangular-lanceolate to acicular apically (sometimes angular in dried material); dorsal leaves borne in 3–4 longitudinal ranks, subulate, with widened bases, sometimes flattened, appressed, contiguous, 1.8–2.5 × ca. 1.5–2 mm. Ventral side of stem with reduced, delicate, translucent, linear-lanceolate, leaves 1.5–2.5 × 0.3–0.5 mm (dried). Erect branches 7–14 cm long, incl. strobilus, 1.2–2 mm thick excl. leaves, with linear-lanceolate, basally slightly denticulate leaves, 3–4.5 × 0.7–1 mm, borne in irregular whorls of 5–7. Strobili 2.5–6 cm × ca. 4.5 mm incl. appressed sporophylls, ca. 7–11 mm with distended sporophylls. Sporophylls borne in alternating whorls of 3–4, forming 6–8 longitudinal ranks, with ovate-rhombic external face with long-acuminate apex, 4–6.5 × ca. 1–1.5 mm, irregularly denticulate. Sporangia ca. 0.8–1.2 mm wide.

Collections studied: MATO GROSSO, Cuiabá, Complexo da Chapada dos Guimarães, at access road to Véu da Noiva, ca. 55°48'W, 15°22'S, ca. 600 m, 25. Nov. 1989, Windisch 5826 (HB, SP).

Distribution and habitat: Endemic to the State of Mato Grosso. In grassland with Iridaceae, Eriocaulaceae, and Drosera, on bare soil with seeping water, and sometimes inundated by water, 600–700 m alt.

Pseudolycopodiella squamata grows locally intermixed with *P. carnosa* and *P. tatei*. In the field the three species can easily be recognized. In *P. squamata* the dorsal leaves have contiguous, clearly delimited, dark green leaf bases covering the stem surface completely, whereas in *P. carnosa* the dorsal leaves are distant, uncovering the pale green, fleshy stem surface. The strobili of *P. squamata* are smaller than those of *P. carnosa*.

All paratypes of *Lycopodiella benjaminiana* P.G. Windisch (1991) belong to the present species.

***Pseudolycopodiella tatei* (A.C. Smith) Holub, Folia Geobot. Phytotax. 26: 93. 1991. Figs. 13,14**

Lycopodium tatei A.C. Smith, Bull. Torrey Bot. Club 57: 180. 1930. - *Lycopodiella iuliformis* (Underw. & Lloyd) B. Øllg. var. *tatei* (A.C. Smith) B. Øllg., Amer. Fern J. 79: 153. 1989. - Type: British Guiana: Mount Roraima, at Philipp Swamp, 5100–5200 ft. 11 Nov. 1927, Tate 350 (NY holotype).

Lycopodium duidae A.C. Smith, in Gleason, Bull. Torrey Bot. Club 58: 311. 1931. - Type: Venezuela: Cerro Duida, Central Camp, 4800 ft., Tate 1010 (NY holotype).

Lycopodiella benjaminiana P.G. Windisch, Bradea 6: 22, Figs. 1–5, 1991. - Type: Brasil, Estado de Mato Grosso, município de Alto Garças, (limite com Pedra Preta), estrada para Itiquira, via Fazenda Ponte de Pedra, Serra da Saudade, ca. 21 Km da BR 364, ca. 53°50'W, 16°50'S, ca. 600–700 m alt., região de cerrado com afloramentos rochosos, vale com vereda e buritis, no campo junto a buritizal, solo encharcado. 18.VII.1991, Windisch 6291 (HB holotype; UFMT, US isotypes). - *Pseudolycopodiella benjaminiana* (P.G. Windisch) B. Øllg., Rodriguesia 63: 481. 2012.

Horizontal shoots closely appressed to the ground, at least to 20 cm long, rooted with short intervals, sparsely to densely branching in the horizontal plane, sometimes forming small mats, bearing stiffly erect, dorsally arising, simple, at least to 30 cm tall strobiliferous branches. Horizontal shoots densely covered on all sides by leaves, 7–13 mm diam. incl. leaves. Stems excl. leaves 2–4 (–5) mm thick (dried), swollen and sometimes flattened above. Leaves of the upper side of horizontal shoots uniform or the lateral ones somewhat widened at the base, usually upward secund and curved, acicular with a subterete to compressed leaf base (angular when dried), or sometimes

Figure 13 – *Pseudolycopodiella tatei*. Venezuela, Auyan-tepui, Guayaraca, Schnee 1449 p.p. (VEN), growth habit.

terete or angular throughout, $4\text{--}9 \times 0.5\text{--}0.8$ (-1.5) mm, with smooth margins. Stem surface readily visible between leaf bases. Leaf bases slightly or not acroscopically adnate, short to long decurrent. Leaves of stem underside pale and membranaceous, to ca. 3 mm long. Erect strobiliferous shoots 3–5 mm diam. including leaves, 1.5–2.5 mm excluding leaves, with uniform, radially arranged leaves. Vegetative leaves of erect shoots borne in alternating, irregular whorls of 3–5, 2–4 mm apart, forming 6–10 obscure longitudinal ranks, appressed to slightly diverging throughout, flattened, subulate, $4\text{--}7 \times 0.5\text{--}1$ mm, evenly tapering, with smooth to slightly denticulate margins. Strobili to 11 cm long, 4–6 mm diam. with appressed sporophylls, to 15 mm diam. with distended sporophylls. Sporophylls borne in alternating whorls of 4–6, forming 8–12 longitudinal ranks, subpeltate, with a basiscopic, compressed membranaceous wing on the stalk, the exterior face with a widely ovate to rhombic basal part and an abruptly to evenly tapering, long apex, $4\text{--}8 \times 1.5\text{--}2.5$ mm, with finely erose-denticulate margins. Sporangia ca. 1.5 mm wide.

Collections studied: BRAZIL. BAHIA: Rio de Contas, Pico das Almas, E slope, Trilha Faz. Silvina-Queiroz, 1400–1500 m, Harley *et al.* 25578 (AAU). MATO GROSSO: Alto Garças (limite com Pedra Preta) estrada para Itiquira, Serra da Saudade, Windisch 6290 (AAU). Felício dos Santos, APA Felício, Mata do Isidoro, surroundings of PE do Rio Preto, near Pico Dois Irmãos, Salino 9898 *et al.* (photo ex BHCB). Salino *et al.* 9963 (photo ex BHCB). PIAUÍ: “Piauhy: Brejo do Correio”, Luetzelburg 18872 p.p. (M). RORAIMA: Vicinity of Auaris, upper slopes of Serra Parima, S of Auaris, 1400–1520 m, Prance *et al.* 9791 (K, M, S, US).

Distribution and habitat: Venezuelan Guiana. Guyana, Brazil: Roraima, Piauí, Mato Grosso, Minas Gerais. Humid campo limpo, and rupestre, humid stream banks, and seepage bogs, alt. 560–1700 m.

This is distinguishable from *Pseudolycopodiella iuliformis* by its swollen and spongy horizontal stems. It occurs at lower elevations than that species. The spongy character of rhizome may represent an adaptation to growth temporarily in shallow water.

A collection at W: São Paulo: Near Campo Grande between Santos and São Paulo, 750 m, Wettstein & Schiffner s.n. (W p.p.) is mixed, mounted together with specimens of *Pseudolycopodiella meridionalis*, has dubious locality information, being far out of the central geographic and habitat range of *P. tatei*. The paratypes of *Pseudolycopodiella benjaminiiana* are referred to *P. squamata*.

Acknowledgements

The authors thank the officers and staff of the herbaria consulted during this study, for the permission to study the material in their care. The first author is grateful for the valuable assistance of Dr. Lana Sylvestre and Dr. Claudine Mynssen at RB for their help during his studies there. The support from the Institute of Bioscience and the Herbarium of the Science Museums, University of Aarhus, and of the Universidade Estadual Paulista, Universidade do Vale do Rio dos Sinos, as well as grants from the Danish Natural Science Council and Brazilian Research Council (Conselho de Desenvolvimento Científico e Tecnológico - CNPq) were essential for the present study. Kirsten Tind prepared figures 5, 7d-f, 8, 9, and 11. Bent Johnsen prepared figures 7a-c, 7g-i.
