Abstract. Birds are the best-known vertebrate group, although many localities in the world are considered to be knowledge gaps. This is the case of many little-known environments in the Amazon biome, the world's largest tropical forest. Here, we present a survey of birds in the upper Purus basin, comprising the municipalities of Manoel Urbano and Feijó in the Brazilian state of Acre, and Boca do Acre and Pauini in the state of Amazonas. In this region, poorly-studied habitats, such as open rainforest dominated by palms or bamboo, still predominate. We recorded 452 bird species during 45 field trips between May and July in 2016, and June to August in 2017. Twenty-four of these species are associated with bamboo habitat, 28 are endemic to the southwestern Amazon basin, and seven are threatened with extinction. This high diversity is typical of the western Amazon basin, one of the richest regions in the world in the number of species, due to the heterogeneity of the local environments. The data presented here highlight the importance of the region for the conservation of birds, including species typical of the western Amazon, some of which are still poorly-known.

Keywords. State of Acre; State of Amazonas; Bamboo habitat; Inambari endemism center.

INTRODUCTION

Birds are the best-known vertebrate group in terms of the identification of species, natural history, and geographic distribution (Silva, 2002; Del Hoyo *et al.*, 2019). This is due to the relative ease of detection of these animals, typically without the need for capture, and the fact that birds occupy a wide range of niches in most environments around the world (Vielliard *et al.*, 2010). Birds have raised human awareness since the time of ancient civilizations, which has also contributed to the accumulation of ornithological knowledge over the centuries. Today, amateur birdwatchers provide professional ornithologists with records as photographs and species lists on virtual platforms, adding to the knowledge of geographic distributions and seasonality (Greenwood, 2007; Bonney *et al.*, 2009; Cottman-Fields *et al.*, 2014; Mason, 1990; Sekercioglu, 2002; Sullivan *et al.*, 2009; Horns *et al.*, 2018). While birdwatching continues to grow, worldwide, and ornithological inventories have increased progressively in recent years, there are

still several regions, especially remote areas, in need of detailed inventory of bird species.

Many locations in the Amazon still lack reliable inventories, especially in the most remote regions, for example, in mountainous regions or difficult to access (Oren & Albuquerque, 1991; Laranjeiras *et al.*, 2019). The existence of this knowledge gap has been reinforced in recent years by the descriptions of 15 new Amazonian species, such as *Nystalus obamai* and *Hemitriccus cohnhafti*, which is a quite unusual development for this otherwise well-documented group (Del Hoyo *et al.*, 2013).

Due to the immense region and the difficulty of access in some places in the Amazon, the concentration of research has generally occurred close to urban centers (Cohn-Haft *et al.*, 1997; Borges & Guilherme, 2000; Guilherme, 2001; Vasconcelos *et al.*, 2007) and on major rivers, such as the Amazon and Negro (Oren, 2001; Cohn-Haft *et al.*, 2007; Borges *et al.*, 2019). The avian fauna of the Amazon region is also quite heterogeneous, reflecting the diversity of habitats, with different flooding regimes and soil types (Braga,

1979; Nelson & Oliveira, 2001), as well as the existence of areas of endemism formed by large rivers that act as geographical barriers to dispersal (Hayes & Sewlal, 2004; Silva et al., 2005; Silva & Garda, 2010).

Since the beginning of the 20th century, the many inventories conducted at remote localities of the basin of the Purus River, in southwestern Amazonia, have revealed an increasingly rich and heterogeneous avian fauna (Snethlage, 1908; Gyldenstolpe, 1951; O'Neill, 1974; Buzzetti, 2010; Guilherme & Dantas, 2011). These studies consisted of sporadic observations and systematic collection of hundreds of copies for museums. Despite the efforts mentioned, no ornithological survey was carried out in the border region of the states of Acre and Amazonas, in southwestern Brazilian Amazonia (Oren, 2001; Guilherme, 2016). Therefore, this study is a pioneer in the region, and in this way, we provide an inventory of the avian fauna of the upper Purus, which straddles the border of the Brazilian states of Acre and Amazonas.

MATERIAL AND METHODS

Study area

We conducted the study in areas that includes parts of the municipalities of Boca do Acre and Pauini, in the state of Amazonas, and Feijó and Manoel Urbano, in state of Acre (Fig. 1). These municipalities are located within the Inambari area of endemism, a zoogeographic region that is limited by the Amazon and Solimões rivers to the north, and the Madeira River to the east, and includes neighboring parts of the Peruvian and Bolivian Amazon (Haffer, 1978; Cracraft, 1985; Silva et al., 2019). We established a sample polygon within radius of 55 km (~328,000 ha) from the intersection of the Purus River with the BR-364 federal highway in the municipality of Manoel Urbano, which was limited to the east by the left margin of the Purus ($08^{\circ}45'S$, $68^{\circ}50'W$) and west by BR-364 ($08^{\circ}38'S$, $68^{\circ}48'W$), with areas on the right margin of the river or to the south of the highway being dis-

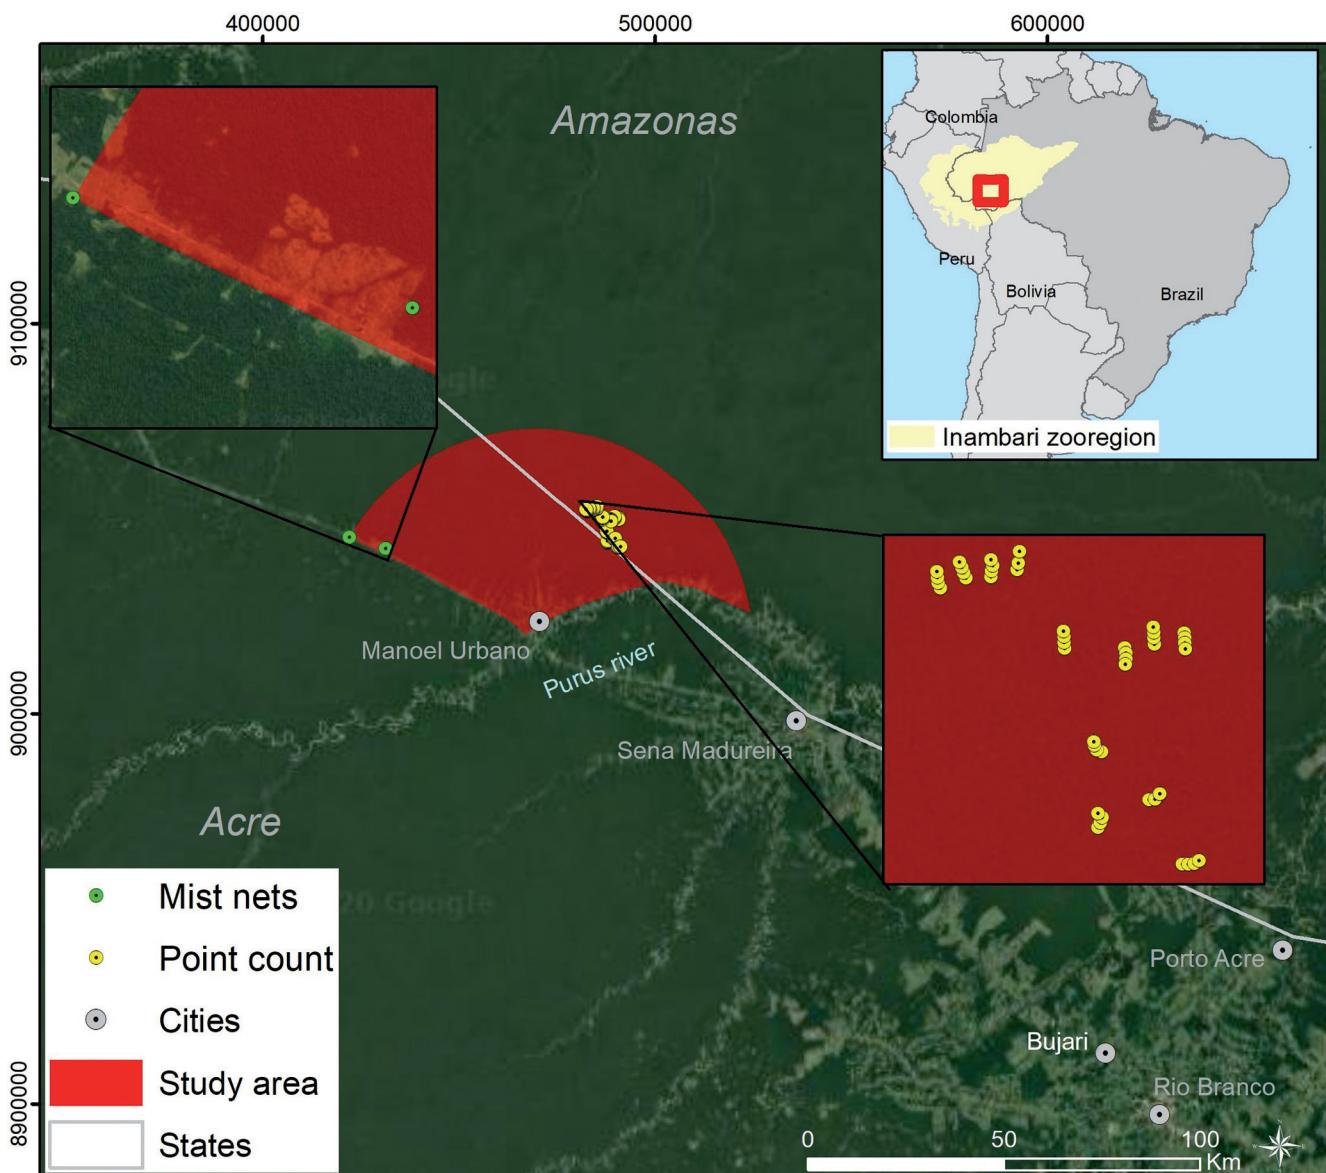

Figure 1. Study polygon, inserted in the zoogeographic zone of endemism Inambari (adapted from Silva et al., 2005, Google Earth credits).

regarded (Fig. 1). The studied area comprises *terra firme* and *várzea* forest with bamboo and enclaves of forest with palms (Fig. 2) (Acre, 2000; IBGE, 2005; Guilherme, 2016).

Survey period and sampling methods

We conducted the research between the years 2016 and 2019 with opportunistic observations (photo and audio recordings) throughout this period, within the sampling polygon (Fig. 1). We obtained the opportunistic data through informal walks along the trails and the margin of the BR-364 highway, and motorboat surveys along stretches of the Purus River. In the eastern portion of the polygon, in May and July of 2016, and in June, July, and August of 2017, we used 48 points counts at 200-m intervals along 12 pre-established trails. The count lasted 15 min at each point. Twelve 1-km transects were also walked for 1 hour on average. We apply both procedures during the morning period, with four point counts and one transect being conducted per morning. We also record some species using playbacks, when there was a need for documentation or visualization, and we recorded audios with Tascam DR100 and Sony PX 820 recorders.

In September 2017, we sampled the western extreme of the polygon with 20 2.5 m × 12 m mist-nets (36 mm

mesh). We placing the nets along two pre-established trails, covering an extension of 264 m, during two days, and opened between 6:30 a.m. and 11:00 a.m. (Fig. 1). The birds we capture, we measure the: beak length, tarsus length, wing length, rectrix length using a digital caliper (precision 0.01 mm), full length with ruler, and body mass with digital balance (precision of 0.1 g), following the protocol of Proctor & Lynch (1993). We collected some individuals for scientific collection and prepared them using the traditional taxidermy method. All specimens collected during fieldwork are now housed at Federal University of Acre (UFAC) in Rio Branco, Acre (Brazil). Specimens were captured under ICMBio/SISBIO authorization Nº 23269-1. We capture and collect the birds by the Comitê de Ética no Uso dos Animais – CEUA (Committee on Animal Research an Ethics) of the Universidade Federal do Acre under process 23107.008809/2016-62. We deposit photographic and audio records on either the WikiAves (WA) or the Fonoteca Casa da Floresta (FCF) online platforms. All the vouchers are referenced in the Appendix.

Species classifications

We classify species in: (1) food guilds, according to Wilman *et al.* (2014); (2) association with habitats dom-

Figure 2. Phytophysiognomies of the study area: (A) *várzea* forest, upper Purus River, (B) *terra firme* forest with habitats dominated by bamboo, (C) *terra firme* forest with low bamboo and palms density (Photos: Diogo C. Casanova, Casa da Floresta collection) and (D) *terra firme* forest with habitats dominated by palms (Photo: Edson Guilherme).

inated by bamboo *Guadua* ssp., according to Kratter (1997), Guilherme & Santos (2009), Lebbin (2013) and Guilherme (2012, 2016); (3) endemism, considering the endemism center Inambari and Andes Foothills or southern Amazon, according to Haffer (1978), Cracraft (1985), Guilherme (2016) and Silva et al. (2019); (4) risk of extinction, according to *Lista Nacional Oficial das Espécies da Fauna Ameaçadas de Extinção* (Brasil, 2014) and Red List for Birds (IUCN, 2020); and (5) dependence on forest environment, being forest-dwelling species, forest generalists and non-forests (adapted from Parker III et al., 1996; Wilman et al., 2014). Scientific nomenclature follows that of the *Comitê Brasileiro de Registros Ornitológicos* (Piacentini et al., 2015).

RESULTS

We recorded a total of 452 bird species in 69 families and 26 orders (Appendix). The main food guilds we recorded were the insectivores (209 species), omnivores (99 species), and frugivores (55 species). Twenty-four of the species (5.31%) are specialists or have some degree of association with bamboo habitat. Overall, 37 of the species (8.19%) are considered to be endemic to the southern margin of the Solimões/Amazon River. Another even more restricted distribution classification refers to the Amazonian zoogeographic zones, with 28 (6.19%) recorded taxa belonging to the Inambari and Andes Foothills. Regarding the categories of forest environments, the predominate of forest-dwelling species (69%), followed by forest generalists (16%) and non-forest (15%). In addition, seven species we recorded are listed as vulnerable to extinction – *Tinamus tao*, *Harpia harpyja*, *Morphnus guianensis*, *Patagioenas subvinacea*, *Ramphastos tucanus cuvieri*, *Ramphastos vitellinus culminatus*, and *Primolius couloni*.

Species accounts

***Crypturellus atrocapillus* (Tschudi, 1844):** It occurs in southeastern Peru, northern Bolivia and Brazil (Cabot et al., 2019), where it can be considered relatively common and with wide distribution (Aleixo & Guilherme, 2010). In Brazil, represented by subspecies *C. a. garleppi* (Berlepsch, 1892), the species was exclusive to Acre (Guilherme, 2009), not appearing in the list of the Mapiá-Inauini National Forest (Silva, 2009) and the Arapixi Extractive Reserve (Mendonça et al., 2010), both located in the municipalities of Boca do Acre and Pauini, in the Amazonas state. However, in the eastern portion of the sampled region, which includes the same municipalities, it was frequent, with records at several sampling points. These records are the first of the species for the Amazonas state, deposited in the WikiAves platform (WA2455992).

***Morphnus guianensis* (Daudin, 1800):** species of wide occurrence in South and Central America, however rare in all its geographic distribution due to its low densi-

ty and because it occupies preferably primary forests (Sanaiotti et al., 2018). An individual was photographed on August 14, 2017 (WA2669908) in the western portion of the study area, on the border between the municipalities of Feijó and Manoel Urbano, state of Acre.

***Accipiter poliogaster* (Temminck, 1824):** although widely distributed throughout South America (Ferguson-Lees & Christie, 2006), in the region it seems to be uncommon, with records in Peru (Schulenberg et al., 2007), one record in Rondônia (WA3312535), and only one record in Acre known until then, the recording of an individual in the municipality of Xapuri by M. Melo and F.I. Godoy (Guilherme, 2016). We record an individual in the eastern portion, on July 6, 2016, in Manoel Urbano, state of Acre.

***Laterallus fasciatus* (Sclater & Salvin, 1868):** Rare Amazonian species with very few records in Brazil. Its distribution extends from Colombia to Peru and northwestern Brazil on the Solimões and Purus rivers, in the Western Amazon (Pinto, 1978; Del Hoyo et al., 1996; Sick, 1997). It's found in the riparian forest, dense undergrowth of humid forests and grassy areas including river islands (Schulenberg et al., 2007). Three couples are recorded on the Purus river bank in the region near the bridge over BR-364 in the municipality of Manoel Urbano, state of Acre.

***Phaethornis bourcieri* (Lesson, 1832):** The species is distributed along the north bank of the Amazon River, extending along the Guianas Shield, Northwestern Brazil, Colombia, Ecuador and eastern Peru, reaching the Acre state (Hinkelmann et al., 2019). Although there are records in Acre territory (Guilherme, 2016), it appears to be more easily recorded through captures with nets than through observation. In the eastern portion of the study area, we record only one individual, on July 23, 2017, through his vocalization.

***Chrysuronia oenone* (Lesson, 1832):** forest hummingbird that occur from Venezuela to Bolivia, with few records in western Brazil (Stiles & Boesman, 2019). Guilherme (2016) mentions records for the species in Acre at Serra do Divisor and Juruá region. In our study the species was recorded in the eastern portion of the study area, foraging in semi-open areas over the years 2016 and 2017, both in portions in the municipality of Boca do Acre, Amazonas and Manoel Urbano, Acre. We were not able to document the species with photographs or sound recordings, however the birds were undoubtedly identified by the males plumage pattern with a contrasting blue on the head, general greenish plumage, and golden rump and rectrices (Schulenberg et al., 2007; Stiles & Boesman, 2019). Our records represent an extension of distribution of 400 km eastwards for the species.

***Heliodoxa aurescens* (Gould, 1846):** species with wide distribution in the Amazon biome, but considered uncommon (Parker III et al., 1996; Schulenberg et al., 2007). In the Inambari region in Brazilian territory, only two

records are known for the Acre state, both on the border with Peru, one in the extreme west Acre (Guilherme, 2016), and the other in the extreme south (Aleixo & Guilherme, 2010). Along our survey, three sightings were made in the eastern portion of the study area, two of which were on the same day (about 800 m apart), in a forest portion in which the species appears to be locally common.

***Steatornis caripensis* Humboldt, 1817:** an individual was observed on the night of May 22, 2016, flying at about 3 m high along a road between the municipalities of Manoel Urbano, Acre and Boca do Acre, Amazonas. This nocturnal bird is associated with caves, where it remains at rest during the day, but during the night the bird can travel great distances in search of fruit (Cleere, 2010). Roca (1994) in a study in Venezuela, verified through telemetry that the species moved 240 km between caves in a single night. This would justify the presence of the species in the region, which has no documented cave environment. It is one of the most unusual records, because in Brazil the species was only known for two localities, both in the Amazonas state, in Manaus (WikiAves, 2008) and in Reserva Natural de Palmari (Whittaker et al., 2004), the latter being approximately 460 km away from our study site. In addition to northern Amazonia and Central America (Trinidad and Panama), *S. caripensis* distribution perimeter extends from Colombian Andes to Bolivia (Thomas & Kirwan, 2019), with some records in the Ucayali and Loreto departments in Peru, bordering the Acre state (Tello et al., 2008), but ~500 km away from the study area.

***Pyrrhura rupicola* (Tschudi, 1844):** species endemic in the Inambari area, considered exclusive of the Acre state in the Brazilian territory (Aleixo & Guilherme, 2010), with records only in the eastern and extreme western portions of Acre (Guilherme, 2016). It is one of the most common parrots in study area, both in the Acre and Amazon regions, recorded on almost every sampling day, with predominant records in slightly disturbed forest areas.

***Forpus xanthopterygius* (Spix, 1824):** although widely distributed in South America, it has disjunct populations, and in the Amazon it is restricted to its western portion (Collar et al., 2019). Despite being quite common in northern and central Peru (Schulenberg et al., 2007), it appears to be rare in the Acre state, where there are only two records (Guilherme, 2016). A group of *Forpus xanthopterygius* was observed on 21st July 2017 in the eastern portion of our study area.

***Nannopsittaca dachilleae* O'Neill, Munn & Franke, 1991:** little known species and of very restricted distribution, occurring only in northwestern Bolivia, eastern Peru and Brazil, exclusively in Acre state (Schulenberg et al., 2007; Guilherme, 2016; Collar & Boesman, 2019). Despite sparse records in the Acre state (DeLuca, 2012), their documentation in Brazilian territory came from specimens collected in the region of Mâncio Lima (Guilherme,

2016). A group was photographed on July 21, 2017 in the municipality of Pauini, constituting a new record for the Amazonas state, expanding its known distribution.

***Celeus spectabilis* Sclater & Salvin, 1880:** species associated with bamboo habitats (Kratter, 1997; Lebbin 2013; Guilherme, 2016), previously considered exclusive to the Acre state in Brazilian territory (Guilherme, 2009). It was recently recorded in Rondônia (Corrêa, 2013). The species was recorded throughout the entire polygon, which shows that it is relatively common in the region.

***Antrostomus sericocaudatus* (Cassin, 1849):** It has two disjunct populations. *Antrostomus sericocaudatus mengeli* (Dickerman, 1975) occurs in southeastern Peru, northwestern Bolivia and Brazil, with sparse records throughout the Amazon, especially in the Acre state (Cleere, 2019). In Acre the species has been recorded only in the eastern portion of the state, on the right bank of the Purus River (Guilherme, 2016). Our records are the first for the left bank of the Purus River in Brazil. In the eastern portion, it proves to be relatively common, easily recorded through its vocalization.

***Picumnus subtilis* Stager, 1968:** endemic species in the Andes Foothills and adjacent lowlands, recently recorded in Brazil (Rego et al., 2009). Considered restricted to the eastern portion of the Acre state, and associated with bamboo habitats (Melo et al., 2015; Guilherme, 2016). The species was common in the Manoel Urbano region, and our records are the first for the left bank of the Purus River in Brazil. Despite being considered associated with bamboo habitats (Guilherme, 2016), we recorded an individual in a secondary forest in the western portion in the municipality of Feijó (WA2849280), and a couple in semi-urban areas of Manoel Urbano (WA3726020), both records in the state of Acre. We do not rule out the possibility of expanding the species' distribution after the suppression (e.g., deforestation, agriculture) in the forest.

***Grallaria eludens* (Lowery & O'Neill, 1969):** one of the most poorly studied Amazonian bird species, it was known from few records limited to the border between Peru and Brazil (Krabbe & Schulenberg, 2019a). There are only four records for Brazil, all in the extreme west of the states of Acre and Amazonas (Whittaker & Oren, 1999; Guilherme, 2016). The species was recorded in the eastern portion of our study area in two occasions, on May 21st and 24th, 2016. Although not seen, it was documented through the recording of the song. Our records represent an expansion of distribution of 400 km to the east, although recent records were made at Chandless State Park (WA2939664), about 100 km from our study site.

***Formicarius rufifrons* Blake, 1957:** terrestrial bird restricted to a few localities in southwestern Peru, Bolivia and Brazil (Krabbe & Schulenberg, 2019b). In Brazil, the species range is restricted to the Acre state, where there were four records in the extreme south and extreme west of the state (Guilherme, 2016). More recently, it

was recorded about 50 km west of Rio Branco (Ramal do Noca) (Melo, 2016). During our survey, we record an individual in the eastern portion of the study site (FCF01683), on May 25, 2016, representing the first record for the Amazonas state. This record represents an extension of distribution of ~200 km to the east.

***Myrmotherula brachyura* (Hermann, 1783):** although widely distributed in the Amazon, in Acre the species was previously recorded exclusively in the border with Peru, in the extreme west of the state (Guilherme, 2016). However, along our survey, *M. brachyura* was quite common in the eastern portion of the study area.

***Myrmotherula assimilis* Pelzeln, 1868:** species associated with várzea forests, present on the margins of the largest Amazonian rivers, such as Purus (Schulenberg et al., 2007). The first record in Acre territory comes from a vocalization recorded in 2001, by Jeremy Minns, in the Alto Juruá Extractive Reserve (XC237143). The first and only specimen from Acre was collected in the western portion of the polygon (AC-936), by EG and DP in *terra firme* forest on 16th of August 2017, in the municipality of Feijó. The capture of this individual in *terra firme* forest reinforces the idea that the species can inhabit environments other than the várzea forest in this region of the Amazon.

***Hypocnemis subflava* Cabanis, 1873:** Bamboo habitat specialist, with home range areas limited to bamboo patches of the genus *Guadua* spp. (Lebbin, 2013; Pedroza & Guilherme, 2019). The species was common throughout the study area, both in the Acre state and in the Amazonas state. We did not record its counterpart *H. peruviana* along our survey, probably a case of local substitution.

***Xenops rutilans* Temminck, 1821:** species with wide distribution in Brazil, but scarce in the Amazon, whose occurrence predominates in its southeast portion, where the taxon *X. r. purusianus* Todd, 1925 ranges from eastern Peru to the Tapajós River (Remsen, 2019). In Acre, is uncommon, with a predominance of records in the far west of the state (Guilherme, 2016). FIG recorded *Xenops rutilans* twice in the eastern portion of the study area (WA3484857).

***Anabazenops dorsalis* (Sclater & Salvin, 1880):** uncommon species, scarce in the Amazonian lowlands (Schulenberg et al., 2007). In Brazil there are occasional records in the states of Mato Grosso, Rondônia and Acre (Guilherme, 2016). Although difficult to visualize, the species was relatively common in the eastern portion of the study area, before the bamboo fruiting in 2016. *Anabazenops dorsalis* was not detected past the bamboo fruiting period. Our records represent the first records for the central region of Acre, and for the Amazonas state.

***Synallaxis cherriei* Gyldenstolpe, 1930:** poorly known species, considered rare, but can be locally common.

In the Inambari region, it has restrict distribution (Schulenberg et al., 2007; IUCN, 2020), with few known records, possibly of the subspecies *S. c. saturata* Carriker, 1934 (Guilherme, 2016). The records presented here are the first for the center of the Acre state and for the Amazonas state. We record the species in the eastern portion on two occasions, always in dense shrub formations at the edge of the forest.

***Lepidothrix coronata* (Spix, 1825):** Two subspecies are recognized for the region of Inambari, *L. c. coronata* (Spix, 1825) to the west of the Purus River and *L. coronata exquisita* (Hellmayr, 1905) to the east, with a clear difference in plumage from the males (Guilherme, 2016). However, all records of the species were auditory, making it impossible to confirm which taxon occurs in the study area, believing that it corroborates with that described for the region.

***Pachyramphus xanthogenys* Salvadori & Festa, 1898:** species considered exclusive to the Acre state in Brazil, where it was thought to occur only in the eastern portion of the state (Guilherme, 2016). One individual was recorded in the Amazonas state, municipality of Boca do Acre, extending the distribution of the species at ~200 km northwest.

***Conioptilon mcilhennyi* Lowery & O'Neill, 1966:** species of distribution restricted to Peru, Bolivia and Brazil, where it was recorded exclusively in the Acre state (Guilherme, 2009; Guilherme, 2012). In our study sites, the species was fairly common, with records in almost all sites that had large trees, including sites in the Amazonas state.

***Cotinga maynana* (Linnaeus, 1766):** a little documented species for the region and also uncommon in the study area. We recorded the bird twice in the eastern portion of the study area. Three males was observed on 25th July 2017. We photographed one individual (WA2960588) and we recorded its wing flap sounds (FCF02224).

***Porphyrolaema porphyrolaema* (Deville & Sclater, 1852):** species with few documented records for Brazil. In the Acre state was known only from two localities (Guilherme, 2016). On 24th June 2017, FIG observed and photographed a couple birds on the eastern portion of our study area (WA2960587).

***Hemitriccus iohannis* (Snethlage, 1907):** in Brazilian territory, *H. iohannis* was thought to occur only on the western and eastern portions of the Acre state (Guilherme, 2016), being virtually absent in the Purus River region. Along our 2016 surveys, few individuals were occasionally recorded in Manoel Urbano, in the riparian forest of the Purus River (FCF01692).

***Muscisaxicola fluvialis* Sclater & Salvin, 1866:** uncommon species of open environments, such as sand banks on river edge (Schulenberg et al., 2007). There

were only two records for the Acre state (Guilherme, 2016). We record an individual in the western portion in a deforested area covered by pioneer vegetation on the edge of BR-364. We collect this individual a voucher specimen (AC-948) and deposited in the UFAC ornithological collection.

Conopias trivirgatus (Wied, 1831): species with few records around the study area, in the Acre state they are concentrated on the border with Peru (Guilherme, 2016). The closest area to our study site where the bird was recorded before was the State Park Chandless (Buzzetti, 2009). We record the species three times at different points in the eastern portion of our study area (FCF02141).

Sublegatus obscurior Todd, 1920: species of forest edge and semi-open environments, rare in the region, with only one record in the Acre state (Guilherme, 2016). We record one individual along our survey, by the road side at the edge of a high-density bamboo forest, in Manoel Urbano (Acre), on May 20, 2016 (WA2445534).

Polioptila plumbea (Gmelin, 1788): although this species has a wide distribution in South America (Atwood et al., 2019), the subspecies that occur in the region, *P. p. parvirostris* Sharpe, 1885 appears to be uncommon, with few records in southeastern Peru (southern limit of taxon distribution) (Harvey et al., 2014) and in the Acre state, with only three records (Guilherme, 2016). However, in our study area it was locally common in almost all the extension of the eastern portion, always in the forest canopy of *terra firme* forest.

Parkerthraustes humeralis (Lawrence, 1867): uncommon species in the region, with only two previous records for the Acre state (Whittaker et al., 2002; Buzzetti, 2009). A group of three individuals was observed and photographed foraging in the canopy of *terra firme* forest in the eastern portion of the study area, on July 21, 2017.

DISCUSSION

The high bird species richness recorded along our survey is related primarily to the location of the study area, given that the Amazon Forest is the world's biologically richest region (Boublí & Hrbek, 2012), and that the Inambari center of endemism is one of its richest in bird species (Hawkins et al., 2006). This region is also dominated by tracts of climax primary forest, which supports many birds typical of preserved environments, which occupy the different forest strata (canopy, medium, litter, understory, and edge), with a high level of landscape connectivity. There is also an ample diversity of environments, with the forest bird community including *terra firme* and *várzea* forest, and specialists in bamboo habitats, although a majority of the species are strict forest species. This group includes many species that depend

on well-preserved forest and are sensitive to environmental change (Parker III et al., 1996). These species include the threatened *Harpia harpyja* and *Tinamus tao*, which are associated with large tracts of mature forest, disappearing rapidly from fragmented habitats and areas with intense hunting pressure (ICMBio, 2018).

The dominant vegetation of the study area, bamboo forest, is quite distinct from the typical Amazonian dense forest formations, with a continuous canopy, and shady understory. Thirty Amazonian bird species are recognized as bamboo habitat specialists (Guilherme & Santos, 2009; Harvey et al., 2014), and the 24 were present in the study area. The association of insectivorous birds with bamboo habitat may guarantee the avoidance of competition with similar species for feeding resources and nest-building materials, such as insectivorous birds of dense edge shrub formations and understory (e.g., Thamnophilidae, Rhynchocyclidae, Furnariidae) (Lebbin, 2007; Pedroza & Guilherme, 2019). In addition, granivorous species such as the Amazonian Parrotlet (*Nannopsittaca dachilleae*) and the Slate-colored Seedeater (*Sporophila schistacea*) appear to accompany the fruiting of *Guadua* bamboo, to feed on its seeds (Collar & Boesman, 2019).

The fruiting of the bamboo may have a major impact on the structure of bird communities given that, following this event, the bamboo suffers massive mortality, provoking profound changes in local environments (Areta & Cockle, 2012). Following the die off of the bamboo, there is an abrupt increase in the penetration of sunlight into the previously shaded understory, and an associated increase in temperature, with the whole stratum disappearing until the development of the new seedlings. Photophobic species of the leaf litter, such as the Elusive Antpitta (*Grallaria eludens*) and the Thrush-like Antpitta (*Myrmothera campanisona*), were absent from the sampling sites following the bamboo fruiting. By contrast, birds associated with clearings such as the Thrush-like Wren (*Campylorhynchus turdinus*) and the Olived-faced Flatbill (*Tolmomyias flaviventris viridiceps*) increased in abundance. Following the die off, bird species associated with bamboo stands became extremely scarce, which was expected – see Areta & Cockle (2012). Habitat fragmentation may also limit the displacement or dispersal of these exclusively forest-dwelling species, which may be limited by the availability of native forest. Furthermore, many other specialist taxa forage in bamboo habitat, which means that it determines an important component of the biodiversity of the forest communities (Guilherme & Santos, 2009).

The local avian fauna also includes a number of species typical of open environments, such as aquatic habitats (Purus River and local streams), roads, and other anthropogenic environments. In fact, a number of species that did not occur originally in the region, such as the Burrowing Owl (*Athene cunicularia*) and the White-tailed Hawk (*Geranoaetus albicaudatus*), have benefitted from the human colonization process, which has resulted in widespread deforestation, principally for the implantation of cattle pasture. The relatively recent phenomenon has become increasingly frequent throughout

the region, and with the spread of deforestation (Souza et al., 2006), bird species adapted to open habitats have become progressively more widespread in the Amazon biome (Guilherme & Czaban, 2015).

The vast majority of the bird taxa that are endemic to the Inambari center of endemism were recorded in the area of the present study (Guilherme, 2016). The Purus River also appears to play a role as a zoogeographic barrier, dividing the ranges of *Lepidothrix coronata coronata* and *L. c. exquisita*, for example (Guilherme, 2009; Guilherme, 2012). However, three taxa considered by Guilherme (2012) to be restricted to the right margin of the Purus were recorded on the left margin in the present study, *Antrostomus sericocaudatus*, *Picumnus subtilis* and *Xiphorhynchus chunchotambo*, which implies that this river may not be a very effective zoogeographic barrier for many taxa (Guilherme, 2016).

The dynamics of the annual flooding, which inundates a number of parts of the local forest, also influences the composition of the local bird community (Haugasen & Peres, 2008), reinforcing the need to evaluate the response of the community, especially given the potential shifts in resource availability. Further research may include additional sampling procedures, including more systematic surveys along the seasonally flooded areas.

Overall, then, our results reinforce the need for further research in the Inambari center of endemism, in particular, in the central and western portions of Amazonas state. We would also recommend further research on the open bamboo habitats at other sites in southwestern Amazonia, in order to better understand the relationship between bamboo specialists and bamboo habitat. As most research in the Amazon basin has tended to focus on dense rainforest habitats (Barlow et al., 2007), the bamboo habitats of southwestern Amazonia is relatively poorly-understood. Further research is clearly needed to better understand the dynamics of the influence of the bamboo cycle on the local avian fauna and its occurrence patterns over the long term, as well as providing important insights for the development of effective conservation measures.

CONCLUSIONS

The presence of threatened species and the high level of endemism found at the study site reinforces the ecological importance of the studied area and the need for its conservation. While the eastern portion of the Acre state, in the vicinity of the capital, Rio Branco, is the most deforested (Guilherme, 2016), the study region, which is located further west is also now beginning to suffer the effects of these impacts. Deforestation in the study region was initially limited to the occupation of areas along rivers and roads by smallholders, although it has accelerated in recent years, mainly through highway construction and the expansion of cattle ranching operations. This implies that the region of the upper Purus River may resemble the east of the state of Acre, in terms of habitat

fragmentation, which will increase the risk of the local extinction of many of the species recorded in the present study that are sensitive to environmental impacts.

ACKNOWLEDGMENTS

F.I.G. thanks the support of Arthur Macarrão, Diogo C. Casanova, Marcelo Ducatti, Vagner Gabriel, Rodrigo Bernardo (layout), Barbara R. Barbosa (layout) and Lys Pereira de Souza. We are grateful to Agrocortex Madeiras do Acre. E.G. and D.P. would like to thank TECMAN – consultoria ambiental e manejo florestal and Secretaria de Meio Ambiente do Estado do Acre – SEMA for the logistical support during this study. We also thank the UFAC Ornithology Laboratory team for the preparation and cataloguing of the collected specimens. We are grateful to prof. Stephen Ferrari for suggestions and English translation.

AUTHORS' CONTRIBUTIONS

F.I.G. and E.G. conceived of the presented idea including the design and implementation of the research. F.I.G., E.G., D.P. and R.A.A.P. conducted the fieldwork. F.I.G. compiled and tabulated the data. All authors contributed to the analysis of the results and to the writing of the manuscript. All authors review and approve the final version of the paper.

APPENDIX

List of bird species recorded in the study area, belonging to the region of the upper Purus River. Voucher: FCF = recording deposited at Fonoteca Casa da Floresta; WA = image or recording deposited on the WikiAves website; AC = specimen collected and deposited in the collection of the Ornithology Museum of the Federal University of Acre.¹ Nomenclature and taxonomy follow CBRO (2015).² Forest dependence: FS = forest-dwelling species; FG = forest generalists; NF = non-forests.³ Feeding guilds: O = omnivorous; G = granivorous, F = frugivores; C = carnivores, S = scavengers; I = insectivores; M = malacophagous; P = piscivores; H = herbivores; N = nectarivorous.⁴ Bamboo specialists.⁵ Endemic species of Inambari center (Inamb), Andes Foothills (AF) or South Amazonia (AMS).⁶ Endangered species at national (BR) or global level (G).⁷ Voucher (documentations): WA = Wiki Aves (photography); FCF = Fonoteca Casa da Floresta (audio recording).⁸ Recording type: O = visual observation; V = vocalization; C = specimen collected; MN = mist net. Municipality: BA = Boca do Acre (AM); PA = Pauni (AM); MU = Manoel Urbano (AC); FE = Feió (AC).
