## ABSTRACT

A new genus and species of Euptychiina (Satyrinae), *Cristalinaia vitoria* Mota, Zacca & Freitas **gen. et sp. nov.**, is described based on three specimens collected in the region of the Cristalino River, Alta Floresta, Mato Grosso, Brazil. This rare species is known only from this region, where it flies inside the dense bamboo patches typical of that area. The last instar larva and the pupa are described; the larva was observed feeding on mature leaves of the common bamboo *Guadua* aff. *paniculata* Munro. urn:lsid:zoobank.org:pub:D61EDE8D-CAE9-41C6-B24D-BB789873566E

## Introduction

In the last decade, a good number of genera in the Neotropical subtribe Euptychiina (Nymphalidae: Satyrinae) have been more or less intensively studied, especially since the start of a large collaborative international effort that began in 2013 and has resulted in 50 publications on the ecology, natural history, taxonomy and evolution of this group (see details in <http://www.flmnh.ufl.edu/museum-voices/euptychiina/>). During the process, the immature stages have been described for several species (e.g., Freitas et al., 2016a,b; Freitas, 2017), new phylogenetic hypothesis have been proposed based on morphology and molecular data (Marín et al., 2017; Espeland et al., 2019), many small and large genera have been reorganized (e.g. Zacca et al., 2017, 2018), and new genera and species have been described from throughout the Neotropics (e.g. Barbosa et al., 2015, 2016; Freitas et al., 2015, 2018; Huertas et al., 2016; Nakahara et al., 2015, 2018, 2019; Zacca et al., 2014; Benmesbah et al., 2018). A number of new species have been identified based on integrative taxonomic approaches targeting cryptic species complexes in large genera, as in the genus *Yphthimoides* Forster, 1964 (Barbosa et al., 2015), while others are clearly distinct based on external morphology, as was the case with the genus *Moneuptychia* Forster, 1964, which increased

from 2 to 8 species in a decade (Freitas et al., 2015 and references therein).

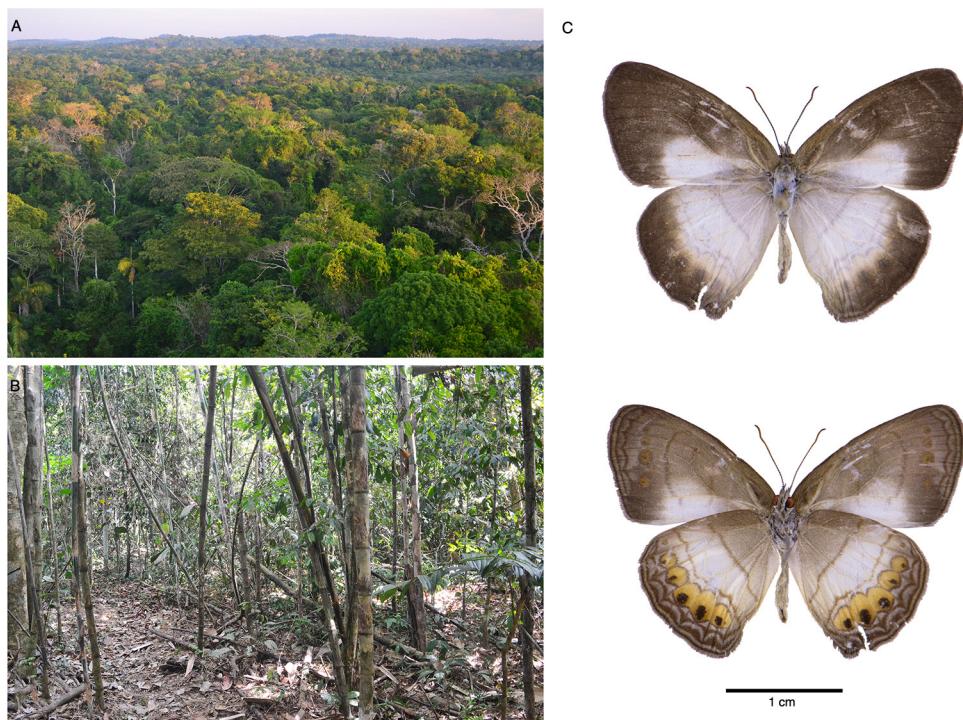

However, in the great majority of the above cases, newly described species were part of cryptic complexes that remained unnoticed in museum drawers, as can easily be observed from lists of examined material, including the types. By contrast, the present study is outstanding by describing a taxon apparently not present in any of the major examined collections. Moreover, this new taxon was initially discovered from a single field-collected larva that was reared to adult, resulting in a highly distinctive satyrine not closely resembling any other known. Subsequent intensive field work in the same region resulted in only two additional specimens, which compose the type series of this new species. Molecular and morphological characters confirm that this new Euptychiina species is seemingly not closely related to any of the known described genera. Accordingly, the present paper describes this southern Amazonian taxon as a new genus and species, and discusses the relevance of the present finding for Euptychiina systematics and conservation of the region.

## Material and methods

### Study site

All three known individuals were collected in the region of the “Cristalino Lodge” (9°35'51"S, 55°55'52"W), located near the west banks of the Cristalino River, in the municipality of Alta Floresta,

**Fig. 1.** Habitat and holotype of *Cristalinaia vitoria* gen. et sp. nov. in the type locality at Cristalino Lodge, Alta Floresta, Mato Grosso, Brazil. (A) A general view of the area; (B) a close view of the bamboo patch where the larva was found; (C) male holotype of *Cristalinaia vitoria* sp. nov. (dorsal above, ventral below).

northern Mato Grosso State (near the border with Pará State in northern Brazil) (Fig. 1A, B). The climate of the region is warm and wet, with average annual temperature of 24 °C and annual rainfall above 2400 mm, with a dry season lasting 3–5 months (Nimer, 1989). The vegetation in the region is transitional from ombrophilous to semideciduous (IBGE, 2004).

#### Morphological studies

The last instar collected in the field was reared in a 500 mL plastic container with fresh leaves of its bamboo hostplant offered *ad libitum*. Photographs of the larva and pupa were taken with a Nikon D3100, and of the last instar cephalic capsule and male genitalia using a Zeiss SteREO Discovery V.20 Stereomicroscope (Zeiss, Germany) in association with the AxioVision Rel.4.8 software for focus-stacking images.

One adult specimen had its abdomen detached and soaked in a heated test tube with 10% potassium hydroxide solution (KOH) for about 3–5 min in *bain marie* before dissection of the genitalia. Wing size was measured from base to apex on the forewing and base to outer margin on the hindwing using a ruler. The terminology for wing venation, wing pattern elements and genitalia follows Zacca et al. (2018). The following abbreviations are used throughout the text: FW – forewing; HW – hindwing; DW – dorsal wings; VW – ventral wings; DFW – dorsal forewing; VFW – ventral forewing; DHW – dorsal hindwing; VHW – ventral hindwing; \* – specimen dissected. The taxonomic higher classification follows Lamas (2004) modified after Peña et al. (2006, 2010) and Wahlberg et al. (2009).

Specimens of different groups of Satyrini have been morphologically examined, photographed and/or dissected by all authors in more than 30 public and private collections (see e.g. Zacca et al., 2018), in addition to the original descriptions of Euptychiina genera (e.g. Forster, 1964). In addition, photographs of Neotropical butterfly type specimens taken by Gerardo Lamas and available in Warren et al. (2013) were also consulted and compared with the new taxon here described.

#### DNA sampling and analysis

Total DNA was extracted from two legs of adults (YPH-0835, BLU883 and BLU1055) using the DNeasy Blood & Tissue Kit protocol (QIAGEN, Düsseldorf, Germany). Total DNA (Deoxyribonucleic acid) was stored in TE buffer at -20 °C. The mitochondrial gene cytochrome c oxidase I (COI – 1498 bp), and the nuclear genes Glyceraldehyde-3-phosphate dehydrogenase (GAPDH – 691 bp) and Ribosomal Protein S5 (RpS5 – 610 bp) for most specimens, were amplified, purified and sequenced using standard techniques (see Barbosa et al., 2015; Silva-Brandão et al., 2005; Wahlberg and Wheat, 2008). The obtained sequences were deposited in GenBank (Benson et al., 2013) (see Table 1 for voucher numbers). All sequences were examined with the program FinchTV v. 1.4.0 (Geospiza, PerkinElmer Inc., Waltham, MA), and posteriorly aligned manually with sequences obtained previously and available on GenBank by using BioEdit v.7.2.4 (Hall, 2013). The final matrix comprised 81 specimens from 58 species of 34 genera (including three specimens from the new genus *Cristalinaia* gen. nov.). The phylogenetic relationships of the new species were estimated using a Maximum Likelihood (ML) analysis. Analyses were run using RAxML (Stamatakis et al., 2008) with 250 thorough searches for the maximum likelihood topology, followed by 1000 rapid bootstrap replicates with the data modeled according to the GTR+CAT model (Stamatakis et al., 2008) and partitioned by gene on the CIPRES portal (Miller et al., 2010).

Fig. 2. Lateral view of the head of *Cristalinaia vitoria* gen. et sp. nov.

**Diagnosis.** *Cristalinaia* gen. nov. differs from all other genera of Euptychiina by the VHW ocelli with very broad orange ocellar rings, reduced black ocellar spots with no pupils (Fig. 1C) and the male 8th abdominal tergite strongly sclerotized, except by the unsclerotized antero-dorsal region (Fig. 4B, C). The female is unknown.

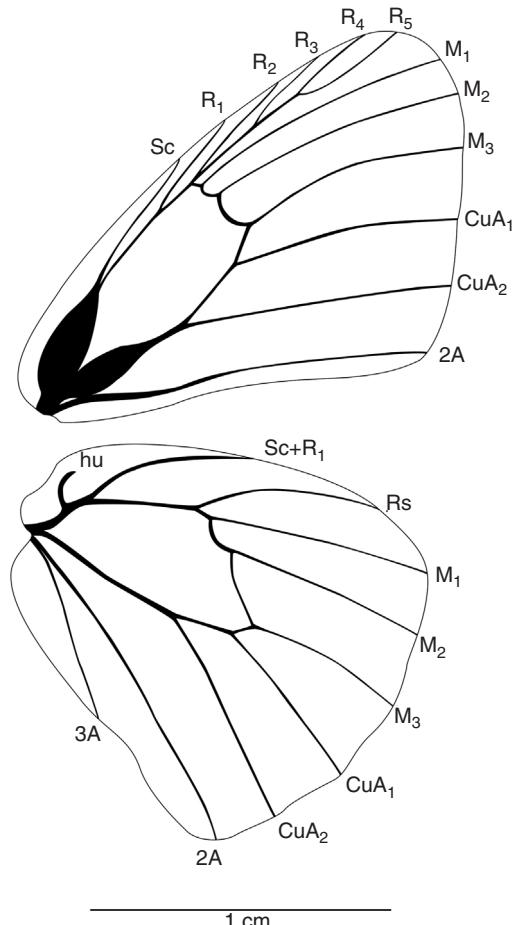

**Etymology.** The generic name is derived from the Cristalino River, a river of dark translucent waters near which the specimens were collected (the word “cristalino” is Portuguese for “crystal clear”, alluding to the translucent waters of the river). It also alludes to the Reserva Particular do Patrimônio Natural Cristalino (Cristalino Private Reserve) and to the “Fundação Ecológica Cristalino” (Cristalino Ecological Foundation), both founded by Vitoria da Riva Carvalho. The gender of the name should be considered feminine.

*Cristalinaia vitoria* Mota, Zacca & Freitas sp. nov. (Figs. 1–6).

**Type material.** Holotype male, deposited in the Museu de Zoologia da Universidade Estadual de Campinas (ZUEC), Campinas, São Paulo, Brazil (Fig. 1C). Labels on the holotype (five labels separated by transverse bars): /HOLOTYPE/BRAZIL, Mato Grosso, Alta Floresta, Cristalino Lodge, 9°35'41"S 55°55'52"W, 2.II.2016, 240–260 m, LLM 280, Luisa L. Mota leg., ex larva/DNA voucher – BLU 883/ZUEC LEP 10648/*Cristalinaia vitoria* Mota, Zacca & Freitas det. 2018/.

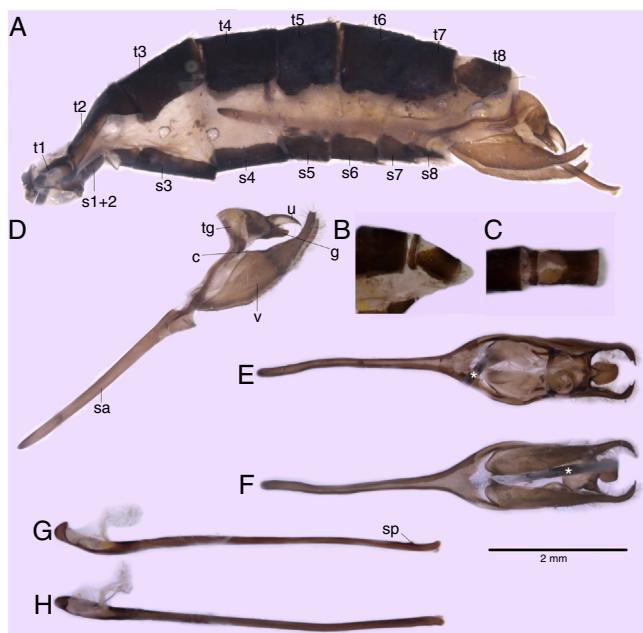

**Paratypes.** 2 males (1 dissected). BRAZIL – Mato Grosso: Alta Floresta, Cristalino Lodge, 9°35'41"S 55°55'52"W, 1 male, 20.IV.2016, LLM 509 (DNA voucher BLU 1055), ZUEC LEP 10650, 1 male, 3.VIII.2018, LLM 52.2018 (DNA voucher YPH 0835), ZUEC LEP 10649\*, Luisa L. Mota leg, ZUEC.

**Diagnosis.** *Cristalinaia vitoria* sp. nov. superficially resembles several other species of Euptychiina (e.g. *Pareptychia* species, *Pseudeptychia* species, *Splendeptychia toynei* Willmott & Hall, 1995, *S. aurigera* (Weymer, [1911]), *S. triangula* (Aurivillius, 1929)) by the white ground color on the wings, but it can be easily distinguished from them by the incomplete median line and four tiny ocelli from  $M_1$  to  $CuA_2$  on the VFW, by the five VHW ocelli between  $M_1$  to  $2A$  that have a very broad orange ocellar ring and black ocellar

spot in the distal half of ring plus a very small ocelli in  $Rs-M_1$ , and the broadened VHW reddish brown marginal line forming crescents in each cell.

**Description.** Head: Brown and glabrous eyes; antennae with 38 flagellomeres ( $n = 1$ ), whitish short scales at base of each flagellomere; labial palpi covered by dark brown elongated scales mixed with creamy scales; third segment with short brown scales and creamy scales in lateral view, first and third labial palpi segments almost same length, second segment 1½ length of third segment (Fig. 2). Thorax: dark brown covered by whitish short scales and elongated filiform scales; coxae and femur covered by whitish short scales, tibia and tarsus covered by dark brown short scales and reduced spines; pair of tibial spurs at distal end of tibia. Wings: FW length: 16.5 mm (HT) – 17–19 mm (PT). **Venation** (Fig. 3): FW with subcostal and media-cubital veins dilated at mid-basal region (more than 10 times wider than mid-apical region of vein) and  $2A$  slightly dilated at mid-basal region (about twice wider than mid-apical region of vein); discal cell half-length of wing length. HW with

**Fig. 4.** Abdomen and male genitalia of *Cristalinaia vitoria* gen. et sp. nov.: (A) Abdomen (lateral); (B–C) 8th abdominal tergite; (B) lateral, (C) dorsal; (D–H) Male genitalia: (D) lateral, (E) dorsal, (F) ventral, (G) Phallus, lateral; (H) Phallus, dorsal. t, tergite; s, sternite; tg, tegumen; g, gnathos; u, uncus; v, valvae; c, costae; sa, saccus; sp, spine. The small white asterisk in E and F indicates the insect pin used for placing the genitalia in position.

developed humeral vein curved in direction to costal margin; discal cell 2/3 length of entire length of wing. **DFW:** ground color brown, whitish area between  $M_3$  and inner margin from base to median region. **DHW:** ground color brown, whitish area between costal and inner margin from base to median region. Elements of ventral wings can be seen throughout transparency. **VFW:** similar to DFW; thin submedian line restricted to discal cell, irregular thin median line from costal margin to 2A, thin crenulated submarginal line from

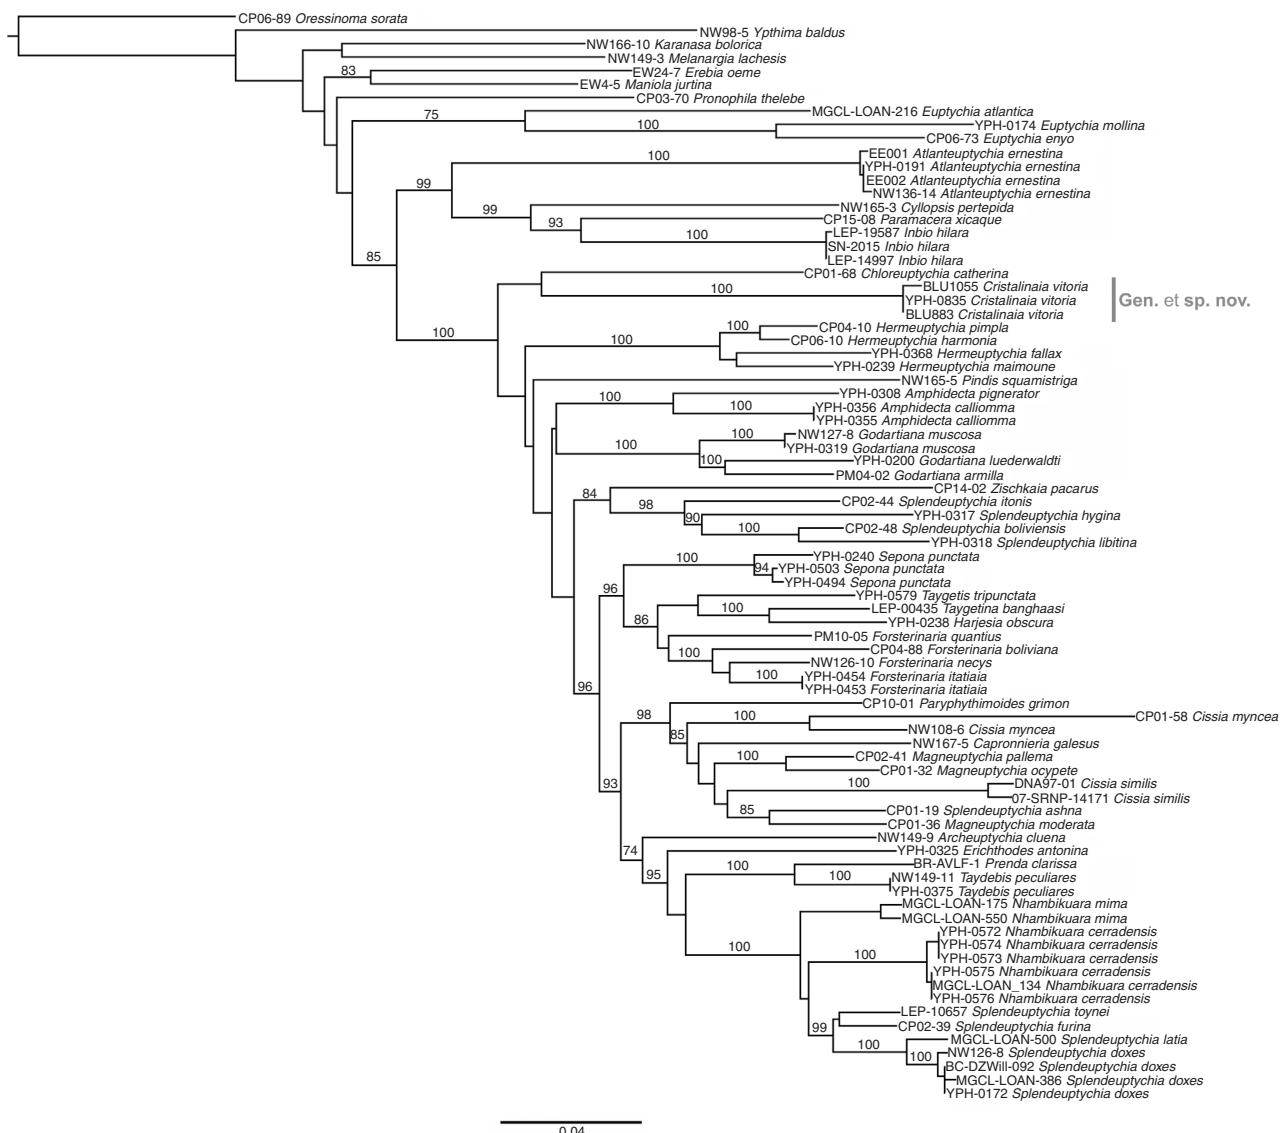

costal margin to tornus, thin marginal line from costal margin to tornus; four tiny ocelli from  $M_1$  to  $CuA_2$ . **VHW:** thin submedian line from costal to inner margin, thin median line restricted to  $CuA_2$  and inner margin, submarginal line crenulated from costal to inner margin, broad marginal line forming crescents in each cell (Fig. 1C); six ocelli from  $Rs$  to 2A, tiny ocellus in cell  $Rs-M_1$ , ocelli from  $M_1$  to 2A with a broad orange ocellar ring surrounding, black ocellar spot distally and with no pupils. **Abdomen:** dark brown covered by whitish short scale; 8th tergite rectangular and strongly sclerotized, excepted by the antero-dorsal unsclerotized region (Fig. 4B, C); 8th sternite reduced. **Male genitalia** (Fig. 4A, D–H): Tegumen subtriangular laterally; appendix angularis absent; ventral projection of tegumen and dorsal projection of saccus fused and angulated at mid-region; anterior projection of saccus well-developed and ventrally open; uncus robust, tapering at apex laterally; gnathos smaller than uncus and robust; valvae trapezoid, 2/3 length of saccus with two reduced spines at apex, covered by small filiform scales, costae reduced; phallus 2/3 length of anterior projection of saccus, vesica without cornuti. **Female:** Unknown.

**Distribution.** *Cristalinaia vitoria* sp. nov. is known only from its type locality in the region of Cristalino Lodge, Alta Floresta, northern Mato Grosso. The site is a private protected area (the “Reserva Particular do Patrimônio Natural Cristalino”).

**Natural history.** This species is extremely scarce; only three individuals have been observed (and collected) over the course of about 600 h of field work, distributed over more than 250 days in all months, from September 2015 to August 2018. In addition, previous collecting trips to the type locality by Keith S. Brown Jr. and AVLF (in February and June 2000) and several butterfly watching groups that visited the area did not detect this species (LLM & AVLF *in prep.*). Based on the very few available data from the three known individuals, *C. vitoria* sp. nov. is restricted to the dense bamboo patches that are common within the forests of the region. The two adults were found within 5 m from each other, although more than two years apart. They were both observed in the shady understory of the bamboo patch at around midday with temperatures above 30 °C, which are not unusual in the area (LLM pers. obs.). Their flight was low (between 0.5 and 1.0 m) and erratic, and they rested on the

**Fig. 5.** Immature stages of *Cristalinaia vitoria* gen. et sp. nov. Last instar: (A) lateral, (B) dorsal, (C) frontal view of last instar head capsule. Pupa: (D) dorsal, (E) lateral.

**Fig. 6.** Maximum Likelihood consensus tree showing the phylogenetic relationships between *Cristalinaia vitoria* gen. et sp. nov. and other Euptychiina genera. Numbers above branches are bootstrap values. Values below 75 are not shown.

upper side of leaves with wings closed. A single last instar (Fig. 5A, B) was found in the field, in a sunny area about 100 m away from where the adults were collected, feeding on mature leaves of the common bamboo *Guadua aff. paniculata*. The larva is entirely green with numerous longitudinal thin light stripes on the body and with a pair of caudal filaments about four times the length of the 10th abdominal segments. The head is green with a pair of short scoli, one on each side of the epicranial/vertical notch (Fig. 5C). The total larval length was 27 mm, the head capsule width was 2.34 mm and the head scoli were of length 1.1 mm. The pupa (Fig. 5D, E) is elongated and smooth, entirely green with thin subtle dorsal dark green stripes and a white line dorsally bordering the wing cases. The ocular caps are very short and rounded, the cremaster is green and the dorsal abdomen is smooth, without projections. The total pupal length was 13 mm.

**Etymology.** The specific name is after Vitoria da Riva Carvalho, in recognition of her pioneering work on the conservation of the southern Amazon, and founder of the Cristalino group (which includes the “Fundação Ecológica Cristalino”, Cristalino Lodge and Cristalino Private Natural Heritage Reserves). The specific epithet should be considered feminine and indeclinable in accordance to the Article 31.2.3 (ICZN, 1999).

#### Phylogenetic analyses

Maximum Likelihood analysis using DNA sequence data from three genes (Fig. 6) supports the description of this new genus and new species, although more sequence data and/or taxa are needed to more confidently refine the relationships of *Cristalinaia* gen. nov. within Euptychiina. Based on the current analysis, the new genus appears as an isolated long branch and cannot be assigned to any of the known genera or any of the Euptychiina clades previously proposed by Peña et al. (2010), Marín et al. (2017) and Espeland et al. (2019) or in ongoing studies (EPB unpublished data), a situation similar to that reported for other studies describing new monobasic genera (Freitas et al., 2016c; Kaminski et al., 2017; Nakahara et al., 2019).

#### Discussion

The wing color pattern of *Cristalinaia vitoria* gen. et sp. nov. is at first glance somewhat similar to that of several other Amazonian satyrines, especially some species of *Splendeuptychia* Forster, 1964. The pattern of the whitish coloration on the DFW and DHW of *Cristalinaia vitoria* gen. et sp. nov. resembles that of *Pseudeuptychia*

*hemileuca* (Staudinger, [1886]), *Splendeuptychia toynei* Willmott & Hall, 1995, *S. aurigera* (Weymer, [1911]), *S. triangula* (Aurivillius, 1929) and most species of *Pareuptychia* Forster, 1964. However, *C. vitoria* sp. nov. can be easily distinguished from all of these species by the curved median line from the Radius to 2A on the VFW, one tiny ocellus in Rs-M<sub>1</sub> and five ocelli with broad orange ocellar ring from M<sub>1</sub> to 2A on VHW.

The male genitalia of *C. vitoria* sp. nov. resembles that found in species of *Stevenaria* Viloria, Costa, Neild & Nakahara, 2016 (see Costa et al., 2016, Figs 40–41), mainly by the long saccus and phallus occupying more than a half of the abdomen length, but there are significant differences in other structures of *C. vitoria* sp. nov., as such the robust gnathos, phallus with small spine at the dorso-apical region (Fig. 4G), apex of the valvae with two reduced spines (Fig. 4D) and vesica without cornuti. Similar long saccus and phallus are known to occur in some clearwing butterflies in the subtribe Godyridina (Danainae: Ithomiini; see Willmott and Freitas, 2006), a group not closely related to Satyrinae (Wahlberg et al., 2009). Another interesting feature of *C. vitoria* sp. nov. is the pattern of sclerotization of the 8th abdominal tergite (Fig. 4B, C); in other species of Euptychiina, the 8th tergite is membranous with a sclerotized half-ring at the anterior region (Nakahara et al., 2016; Willmott et al., 2018; TZ pers. obs.). The above cited characteristics make *C. vitoria* gen. et sp. nov. unique among the Euptychiina. Other characters of the male genitalia and wing color pattern were also inconclusive to assign *C. vitoria* gen. et sp. nov. to any known Euptychiina clade, agreeing with the molecular data.

Concerning the immature stages, the last instar is at first glance similar to those of several Euptychiina with green-striped larva, especially those of *Zischkaia pacarus* (Godart, [1824]) and *Godartiana muscosa* (A. Butler, 1870) (Freitas and Peña, 2006; Freitas et al., 2016a, 2016b; Zanca et al., 2017; See et al., 2018). However, the shape of last instar head scoli and the pupal profile are quite distinct from all these species. In fact, the larval color pattern is very similar to the ground color present in the elongated leaves of bamboos and grasses, suggesting that camouflage could be involved (see also Freitas, 2017 for a similar case), explaining why several unrelated species of Euptychiina are convergent in larval coloration.

Finally, it is important to draw attention to the conservation status of the entire region of the Cristalino River in the Alta Floresta municipality. The forests of the region have been highly impacted in recent decades, especially in the western frontier of the Parque Estadual Cristalino (Cristalino State Park (de Paulo et al., 2015)). The regional landscape is now dominated by forest fragments embedded in a matrix of pastures, resulting in obvious loss of habitat quality and major changes in local climate (Dubreuil et al., 2012). However, in the “Reserva Particular do Patrimônio Natural Cristalino”, the type locality of *C. vitoria* gen. et sp. nov., the forests are still preserved; moreover, the area is contiguous to the large Cristalino State Park and, hopefully, the total preserved area (summing 184,000 ha) is large enough to protect the new taxon here described, as well as the entire regional biota. This work thus underlines the importance of conservation efforts in the Southern Amazon, where other remarkable, phylogenetically distinctive species surely await discovery.

## Author contributions

Manuscript idealization: AVLF and LLM; collecting and immature stages rearing: LLM; morphology: TZ; phylogeny: EPB; writing, review and figures: All authors.

## Conflicts of interest

The authors declare no conflicts of interest.

## Acknowledgements

The authors thank Cristalino Lodge and Fundação Ecológica Cristalino for logistic support. Keith Willmott carefully read the last version of the manuscript and gave valuable suggestions. The ICMBio provided the collecting permits (10438-1, 7462-1, 8969-1). AVLF acknowledges support from FAPESP (Biota-Fapesp grants 2011/50225-3 and 2013/50297-0), from the Brazilian Research Council – CNPQ (fellowship 303834/2015-3), from the National Science Foundation (DEB-1256742) and from USAID and the U.S. National Academy of Sciences (NAS) under the PEER program (Sponsor Grant Award Number: AID-OAA-A-11-00012). EPB and TZ thank FAPESP for Pos-Doc fellowships (2016/15873-8, 2017/02264-6, respectively). LLM thanks CAPES for a doctoral fellowship. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior – Brasil (CAPES) – Finance Code 001. This publication is part of the RedeLep ‘Rede Nacional de Pesquisa e Conservação de Lepidópteros’ SISBIOTA-Brasil/CNPq (563332/2010-7). Butterfly species are registered in the SISGEN (ACBC599).
