## Abstract

This study aimed to investigate the therapeutic mechanism of treating SMMC-7721 liver cancer cells with magnetic fluid hyperthermia (MFH) using Fe<sub>2</sub>O<sub>3</sub> nanoparticles. Hepatocarcinoma SMMC-7721 cells cultured *in vitro* were treated with ferrofluid containing Fe<sub>2</sub>O<sub>3</sub> nanoparticles and irradiated with an alternating radio frequency magnetic field. The influence of the treatment on the cells was examined by inverted microscopy, MTT and flow cytometry. To study the therapeutic mechanism of the Fe<sub>2</sub>O<sub>3</sub> MFH, Hsp70, Bax, Bcl-2 and p53 were detected by immunocytochemistry and reverse transcription polymerase chain reaction (RT-PCR). It was shown that Fe<sub>2</sub>O<sub>3</sub> MFH could cause cellular necrosis, induce cellular apoptosis, and significantly inhibit cellular growth, all of which appeared to be dependent on the concentration of the Fe<sub>2</sub>O<sub>3</sub> nanoparticles. Immunocytochemistry results showed that MFH could induce high expression of Hsp70 and Bax, decrease the expression of mutant p53, and had little effect on Bcl-2. RT-PCR indicated that Hsp70 expression was high in the early stage of MFH (<24 h) and became low or absent after 24 h of MFH treatment. It can be concluded that Fe<sub>2</sub>O<sub>3</sub> MFH significantly inhibited the proliferation of *in vitro* cultured liver cancer cells (SMMC-7721), induced cell apoptosis and arrested the cell cycle at the G<sub>2</sub>/M phase. Fe<sub>2</sub>O<sub>3</sub> MFH can induce high Hsp70 expression at an early stage, enhance the expression of Bax, and decrease the expression of mutant p53, which promotes the apoptosis of tumor cells.

Key words: Fe<sub>2</sub>O<sub>3</sub>; Magnetic nanoparticles; Magnetic fluid hyperthermia; Hepatocarcinoma cells; Liver cancer

## Introduction

In 1997, Jordan et al. (1) first reported a novel method of using magnetic fluid hyperthermia (MFH), which is carried out through the combination of nanotechnology and magnetic induction hyperthermia, to treat tumors, and remarkable results were obtained. This therapy is also known as targeted intracellular hyperthermia. Yanase et al. (2) and Shinkai et al. (3) subsequently wrapped the magnetic nanoparticles in lipid membranes to generate magnetic liposomes (MLs) as intracellular hyperthermia agents with increased efficacy. It was found in later studies (4) that intracellular hyperthermia could also trigger immune responses.

One of the therapeutic mechanisms of MFH in killing tumor cells is the induction of cellular apoptosis (5,6). Apoptosis is a physiological orderly cell death with a very complex mechanism that is subject to a variety of promoting

and inhibiting factors. A variety of oncogenes and tumor suppressor genes have been demonstrated to regulate apoptosis, such as *p53*, *Bcl-2*, *c-Myc*, and *transforming growth factor (TGF)-β* (7,8). The *Bcl-2* family has received extensive attention, since it appears to be the common destination of various apoptosis pathways and thus regulates apoptosis. These genes play important roles not only in the formation and development of tumors but also in tumor therapies. Regulation of apoptosis by the *Bcl-2* and *Bax* genes, both of which are members of the *Bcl-2* family, has increasingly become a research topic in molecular biology. *Bcl-2* is antiapoptotic and its overexpression (*Bcl-2*-*Bcl-2*) results in apoptosis inhibition and cell survival, whereas *Bax* is proapoptotic (9,10), and its overexpression (*Bax*-*Bax*) leads to cell death. However, the expression of the apoptosis suppressor gene *Bcl-2* is low or nonexistent in

hepatoma cells (11,12), whereas Bax is widely distributed in various organs including normal liver tissues, which indicates that Bax is probably an important apoptosis-regulating gene (13). Bai et al. (14) reported the abnormal expression of Bax in Hodgkin's disease. Bcl-2 and Bax have been shown to have an important influence in regulating the apoptosis of gastric cancer, prostate cancer, ovarian cancer, and other tumor cells (15). However, correlation of the apoptosis index with Bcl-2, Bax, and related proteins in hepatocellular carcinoma has not been reported (16). In addition, the p53 gene not only regulates cell proliferation and differentiation but also participates in regulating apoptosis. The wild-type p53 gene promotes apoptosis, whereas the mutant p53 gene inhibits apoptosis (17). The mutant p53 can downregulate the expression of Bcl-2 (18). Guo et al. (19) reported no significant relationship between Bax and p53. The abnormal expression of Bax and p53 in hepatocellular carcinoma indicates that the two proteins may be associated with liver cancer but have different mechanistic pathways.

In this study, hepatocarcinoma cells were treated *in vitro* with ferrofluids containing various concentrations of Fe<sub>2</sub>O<sub>3</sub> nanoparticles and irradiated with an alternating magnetic field. The influence of the treatment on the cells was examined by inverted microscopy, transmission electron microscopy (TEM), methylthiazolotetrazolium (MTT) viability assay and flow cytometry. To further evaluate the therapeutic mechanism of the treatment, Hsp70, Bax, Bcl-2 and p53 were detected by immunocytochemistry (IC) and reverse transcription polymerase chain reaction (RT-PCR). The experimental results are expected to establish a reliable basis for the clinical treatment of liver cancer.

## Material and Methods

### Reagents and equipment

SMMC-7721 human hepatoma cells were purchased from the Shanghai Institute of Biology and Cell Biochemistry, Chinese Academy of Science. RPMI 1640 culture medium was purchased from Gibco-BRL (USA). Trypsin (0.25%) was purchased from AMRESCO (USA). MTT and diethyl bicarbonate (DEPC) were purchased from Sigma (USA). Giemsa dye was purchased from Chroma (USA). AMV reverse transcriptase, dNTP, Oligo(dT)18, Taq DNA polymerase, 100 bp DNA ladder, RNasin (40 U/L), and RNase-free DNase I were all purchased from Takara Co. (China). The immunocytochemical reagents, streptavidin-peroxidase (SP) staining kit and liquid aminoethyl carbazole (AEC) enzyme substrate visualization kit were purchased from Beijing Zhongshan Biotechnology Co., Ltd., China. All biochemical reagents used in this study were of analytical grade.

A PTC-100 thermal cycler, Multiskan MK3-353 enzyme linked immunosorbent assay (ELISA) reader and Vantage SE fluorescence-activated cell sorting (FACS) system (USA) were used. An inverted microscope and JEM-2010

high-resolution transmission electron microscope (JEOL, Japan) were used. An SP-04C high-frequency induction heater (Shenzhen Shuangping High-Frequency Heater Factory, China) was used with the following operating parameters: frequency = 200 kHz; power = 4 kW; output alternating heating current = 100-350 A.

### Experiment

The experiment was divided into 4 groups. The blank group contained the RPMI 1640 culture medium only (control group A), while a second control group with the same composition received magnetic irradiation (control group B). The third group contained 8 g/L Fe<sub>2</sub>O<sub>3</sub> nanoparticle ferrofluid in RPMI 1640 medium but was not heated (spiking group). The final group contained various concentrations of Fe<sub>2</sub>O<sub>3</sub> nanoparticle ferrofluid (2, 4, 6, 8 g/L) in RPMI 1640 and was heated by magnetic irradiation (MFH group). The Fe<sub>2</sub>O<sub>3</sub> nanoparticle ferrofluid was prepared using sterile RPMI 1640 medium. SMMC-7721 cells in the logarithmic proliferation phase were used in the experiments. MFH heating was carried out by placing the sample on the coil plate of the SP-04C high frequency heater and applying a high frequency alternating current (AC) alternating magnetic field (200 kHz, 4 kW, output current 300 A).

### Preparation and characterization of Fe<sub>2</sub>O<sub>3</sub> magnetic nanoparticles

The magnetic nanoparticles used in the present study were made of maghemite ( $\gamma$ -Fe<sub>2</sub>O<sub>3</sub>), which was synthesized according to the following procedures: 1) Fe<sub>3</sub>O<sub>4</sub> nanoparticles were prepared. Briefly, a combined solution of FeCl<sub>3</sub> (1 mol/25 mL water) and FeSO<sub>4</sub>·7H<sub>2</sub>O (0.6 mol/25 mL water) was stirred under nitrogen followed by the rapid addition of 15 mL ammonia (25%) and further stirring for 15 min. The dark precipitate of magnetite particles (Fe<sub>3</sub>O<sub>4</sub>) that formed was isolated using a permanent magnet and dried under vacuum. 2)  $\gamma$ -Fe<sub>2</sub>O<sub>3</sub> nanoparticles were prepared as follows. The Fe<sub>3</sub>O<sub>4</sub> nanoparticles were suspended in solution of Fe(NO<sub>3</sub>)<sub>3</sub> at a concentration of 5 g/L. The particles were oxidized into maghemite at 90°C with O<sub>2</sub> for 30 min. When the dark precipitate became brown, the  $\gamma$ -Fe<sub>2</sub>O<sub>3</sub> nanoparticles were isolated with a permanent magnet. The nanoparticle diameters (ranging from 10 to 20 nm) were controlled by varying the proportion of iron (II) and iron (III), as previously described (20).

### Microscopic observation of cell morphology

Cells were added to the culture medium (5 mL) corresponding to each experimental group. Each sample of the MFH group received 1 h irradiation. All samples were then further cultured for 48 h at 37°C in an incubator with 5% CO<sub>2</sub>, and saturated humidity. Cell morphology was observed and photographed using an inverted optical microscope and TEM.

### Cell proliferation rate measured by MTT

The SMMC-7721 cells were digested with 0.25% trypsin and prepared as a cell suspension. The cell concentration was adjusted to  $6 \times 10^4$ /mL and 100  $\mu$ L suspension ( $6 \times 10^3$  cells) was added to each well of a 96-well culture plate. Each group was assigned 8 wells, and 24 h after cell seeding, 100  $\mu$ L of the corresponding medium was added. The control group B and the MFH group were irradiated for 1 h. After culturing for 48 h, MTT (20  $\mu$ L per well) was added. The mixtures were further cultured for 4 h and the liquids were discarded. To each well 160  $\mu$ L dimethylsulfoxide (DMSO) was added, the plate was shaken for 10 min, centrifuged at 2500 g for 10 min, and the supernatant liquids were transferred to the wells in another 96-well plate. The absorbance (A) at 493 nm was measured using an automatic ELISA reader. The inhibition rate (%) =  $(1 - A_{\text{experimental group}}/A_{\text{control group}}) \times 100$  and the proliferation rate (%) =  $(A_{\text{experimental group}}/A_{\text{control group}}) \times 100$ .

### Flow cytometry analysis

SMMC-7721 cells ( $3 \times 10^5$ /mL) were inoculated into 50 mL flasks (2 mL per flask) and cultured for 24 h. A 3 mL volume of culture medium from control group A, the spiking group and the MFH group were added to individual flasks. The MFH group was irradiated for 1 h while the other two groups were placed at room temperature (26°C) for 1 h, after which all groups continued in culture for 48 h. The cells were collected, washed twice with phosphate buffered saline (PBS), then fixed with 70% ethanol at 4°C for >24 h. Before flow cytometry, cells were washed twice with PBS, resuspended in 0.5 mL propidium iodide (PI; 0.05 g/L PI, 0.1 g/L RNase A) for staining 30 min at 26°C in the dark. They were then passed through a 300-mesh filter and analyzed with the flow cytometer. Data were analyzed using the Lysis II software (Becton-Dickinson, USA) software.

### TUNEL apoptosis assay

DNA fragmentation was detected by terminal deoxynucleotidyl transferase dUTP nick end labeling (TUNEL) assay, using the DeadEnd™ Fluorometric TUNEL System (Promega Corporation, USA). Cells ( $5 \times 10^3$  per well) were plated onto 96-well flat bottom plates (Corning Inc., USA) and allowed to attach overnight prior to treatment. The assay was performed as previously described by Kristjansdottir (21). Experiments were performed in triplicate.

### Immunocytochemistry detection of Hsp70, Bax, Bcl-2 and p53 expression

*Cells seeding and handling.* The SMMC-7721 cells ( $3 \times 10^5$ /mL) were inoculated into 6-well plates where each well carried a coverslip. A volume of 2 mL cell suspension and 3 mL RPMI 1640 culture medium were added to each well. The mixtures were cultured for 24 h until the cells attached to the coverslip and were then assigned to the control group A and the MFH group. The wells of the MFH

group were irradiated for 1 h. After further culturing for 24-48 h, the coverslips were removed, washed twice with pH 7.2-7.4 PBS, air dried, fixed with cold acetone for 5-10 min, air dried (or blow dried), fixed onto 26  $\times$  76 mm<sup>2</sup> slides using neutral gum, and stored at -20°C.

*Immunocytochemical staining.* The cell-seeded coverslips were washed twice with PBS and dried. An appropriate amount of 3% H<sub>2</sub>O<sub>2</sub> was added dropwise and the mixture was incubated for 10 min at 37°C in a 100% humidity incubator, washed with distilled water and soaked in PBS for 5 min. Normal goat serum blocking solution was added dropwise and the mixture was incubated at room temperature for 15 min, then decanted (but not washed). From this point on, the dilute solution of mouse anti-human antibodies (Hsp70, Bax, bcl-2, p53) was added dropwise and the mixture was incubated at 37°C for 2 h; then the biotinylated goat anti-mouse secondary antibody was added dropwise and the mixture was incubated at 37°C for 15 min; and finally the working solution of horseradish peroxidase (HRP)-labeled streptavidin was added dropwise and the mixture was incubated at 37°C for 15 min. Each incubation stage was followed by washing three times, 3 min each time, with PBS. Finally, freshly prepared AEC solution was added at room temperature and the mixture was examined under the microscope while staining for 10-30 min. The mixture was then extensively flushed with tap water for 10 min and restained with hematoxylin for 40-60 s. The appropriate timing was determined by microscopic observation. The re-staining step was omitted if observation indicated nuclear expression. The stained coverslip was sealed with ClearMount (Shanghai Sangge Biological Technology Co., Ltd., China) and heated at 70-80°C in an oven for 10-20 min, then examined microscopically and photographed.

### RT-PCR detection of Hsp70 expression

*RNA concentration, purity and integrity.* The SMMC-7721 cells cultured in groups were extracted according to the Trizol manual and total RNA was purified. The RNA concentrations corresponding to the samples were calculated. RNA samples (5  $\mu$ L) were loaded in buffer solution and electrophoresed in 0.8% agarose denaturing gel. The presence of at least two full strips indicated that the RNA quality was sufficient to enable the reverse transcription experiment to continue.

*Reverse transcription.* The reverse transcription reaction system (total volume 20  $\mu$ L) consisted of the RNA samples (5  $\mu$ L), Oligo dT<sub>18</sub> (1  $\mu$ L), dNTP (10 mM, 2  $\mu$ L), RNasin (0.5  $\mu$ L), AMV (1  $\mu$ L), 5 $\times$  buffer (4  $\mu$ L), and DEPC water (13.5  $\mu$ L). The RNA sample was pre-denatured at 65°C for 10 min and placed in an ice bath for 10 min before its final addition to the reaction system. The reverse transcription then proceeded at 42°C. The mixture was inactivated at 99°C for 5 min and then stored at -20°C.

*PCR amplification.* 1) Primer customization and dilution: Hsp70 and  $\beta$ -actin primers were synthesized by

**Table 1.** PCR reaction system

Material	Volume ( $\mu\text{L}$ )
10 $\times$ PCR buffer	2
dNTP	0.5
Hsp70 forward primer	1
Hsp70 reverse primer	1
$\beta$ -actin forward primer	1
$\beta$ -actin reverse primer	1
cDNA	4
TaqE	0.5
$\text{MgCl}_2$	2

Shenneng Bocai Biotechnology Co., Ltd (China) as previously described (22). The primers were diluted to 20 pmol/ $\mu\text{L}$ , divided into aliquots and stored at  $-70^\circ\text{C}$  until use. 2) PCR reaction system (Table 1): the reaction system was diluted with DEPC water to 25  $\mu\text{L}$ . cDNA was first denatured at  $94^\circ\text{C}$  for 2.5 min and then added to the reaction system. Amplification was carried out on the PTC-100 cycler (MJ Research Watertown Inc., USA). The amplification cycle for Hsp70 included denaturation at  $94^\circ\text{C}$  for 30 s, annealing at  $59^\circ\text{C}$  for 30 s and extension at  $72^\circ\text{C}$  for 45 s, for a total of 25 cycles; and then extension at  $72^\circ\text{C}$  for 10 min and storage at  $-20^\circ\text{C}$ . The PCR conditions for  $\beta$ -actin were identical to those of Hsp70, except for annealing at  $64^\circ\text{C}$  and a total of 24 cycles. In the control experiment, distilled water was used as a negative control instead of cDNA in the PCR reaction system. Untreated MCF-7 cells that expressed Hsp70 were used as a positive control. Each DNA amplification was performed in the presence of positive and negative controls to ensure the reliability of the results. 3) Agarose gel electrophoresis: agarose (0.5 g) was added to  $0.5 \times$  Tris-borate-EDTA (TBE) buffer (25 mL) to prepare 2.0% agarose gel. TBE

was added to adjust the final concentration to 0.5  $\mu\text{g}/\text{mL}$ . When the temperature of the gel solution was approximately  $50^\circ\text{C}$ , the gel was poured while avoiding air bubbles and the comb was inserted. After solidification, the gel was placed in the electrophoresis tank. Samples were spotted (5  $\mu\text{L}$  PCR product, 1  $\mu\text{L}$  loading buffer) and electrophoresed in  $0.5 \times$  TBE buffer at 80 V. After 30 min, the electrophoresis products were examined under UV light, scanned and photographed.

### Statistical analysis

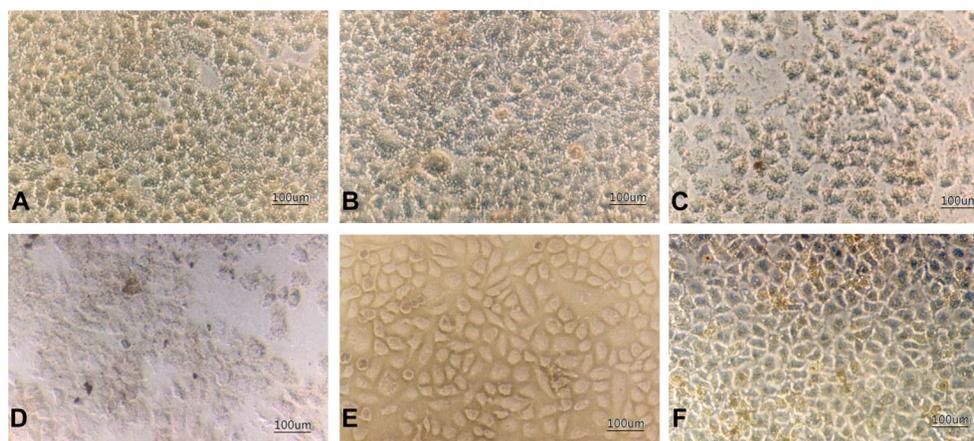

Data are reported as means  $\pm$  SD. The Poisson distribution was used to evaluate differences between the control group and treatment groups. ANOVA was performed between treatment groups. All statistical analyses were performed using SAS 8.1 and SPSS version 10.0.

## Results

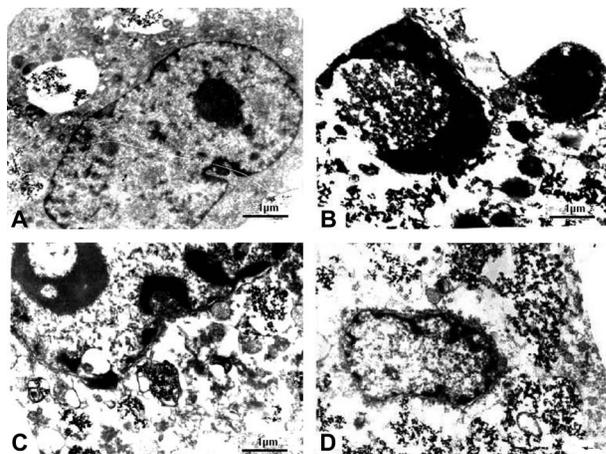

### Cell morphological changes

It was observed under the inverted microscope that the cells of control group A exhibited uniform size with no cell rupture or fragmentation. The cells were abundant and attached well. The spiking group was essentially the same as control group A except that some magnetic material had entered into or deposited among the cells. The cells of the MFH group showed notable changes in morphology. The temperature increase was positively correlated with the concentration of the  $\text{Fe}_2\text{O}_3$  nanoparticle ferrofluid (2 g/L  $\rightarrow$   $39^\circ\text{C}$ , 4 g/L  $\rightarrow$   $41^\circ\text{C}$ , 6 g/L  $\rightarrow$   $43^\circ\text{C}$ , 8 g/L  $\rightarrow$   $47^\circ\text{C}$ ). The number of normal cells gradually decreased whereas necrotic cells and cell debris became abundant. Cell attachment was poor or absent. The magnetic material was increasingly deposited, and in some cases the cells were not visible (Figure 1).

Electron microscopy results showed that the control

**Figure 1.** Morphology of SMMC-7721 cells under inverted microscope ( $100 \times$ ). A, 2 g/L  $\text{Fe}_2\text{O}_3$  MFH group; B, 4 g/L  $\text{Fe}_2\text{O}_3$  MFH group; C, 6 g/L  $\text{Fe}_2\text{O}_3$  MFH group; D, 8 g/L  $\text{Fe}_2\text{O}_3$  MFH group; E, 8 g/L  $\text{Fe}_2\text{O}_3$  spiking group (no radiation); F, control group A (RPMI 1640 culture medium only). MFH: magnetic fluid hyperthermia.

**Figure 2.** Morphology of SMMC-7721 cells after treatment. A, spiking group (8 g/L Fe<sub>2</sub>O<sub>3</sub>, no radiation); B-D, MFH groups (4, 6 and 8 g/L Fe<sub>2</sub>O<sub>3</sub>, respectively). MFH: magnetic fluid hyperthermia.

group A had normal cell morphology. The cells of the spiking group also appeared normal with nanomaterials visibly deposited inside and outside the cells. The hepatoma cells of the MFH group exhibited chromatin condensation, cytoplasmic vacuolization, and formation of apoptotic bodies. Nanomaterials were visibly deposited in the nucleus, cytoplasm and lysosomes (Figure 2), and were confirmed to be Fe<sub>2</sub>O<sub>3</sub> nanoparticles by spectral analysis (Figure 3).

### MTT experimental results (Table 2)

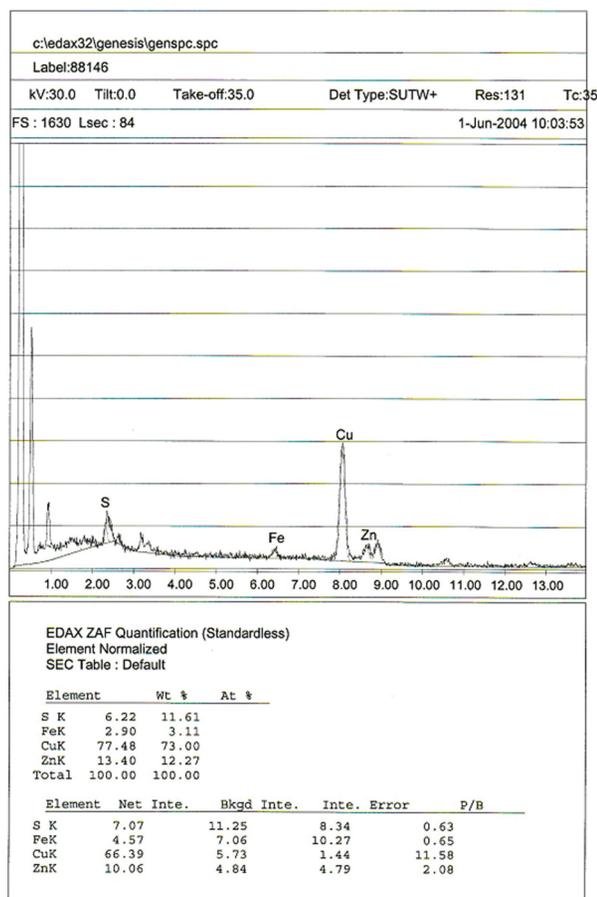

The viability of each group was calculated from the measured absorbance (A) values as cell survival rate (%) =  $(A_{\text{average, experimental group}}/A_{\text{average, control group}}) \times 100$ . The results of the MTT assay are shown in Figure 4. MFH using Fe<sub>2</sub>O<sub>3</sub> nanoparticles significantly inhibited the proliferation of SMMC-7721 cells. The inhibition rate was clearly dependent on the ferrofluid concentration, and the maximum inhibition rate reached 81.77%. A significant difference ( $P < 0.05$ ) was noted between the MFH group and all other groups (control group A, control group B, and spiking group) (Figure 4).

### Flow cytometry

The flow cytometry results showed that in the MFH group after 48 h, obvious hypodiploid DNA (apoptotic) peaks appeared before the G1 peak, and the apoptosis rate increased with rising concentration of the Fe<sub>2</sub>O<sub>3</sub> nanoparticle ferrofluid. The cell cycles were arrested at the G2/M phase to various degrees. The control group and the spike group showed no obvious apoptosis peaks (Figure 5).

### TUNEL assay results

The TUNEL assay results revealed many apoptotic cells

**Figure 3.** Energy spectrum of intracellular magnetic nanoparticle deposits in SMMC-7721 cells.

in the MFH groups. The apoptosis rate increased with rising concentration of the Fe<sub>2</sub>O<sub>3</sub> nanoparticle ferrofluid. However, fewer, or no, apoptotic cells were found in the Fe<sub>2</sub>O<sub>3</sub> nanoparticle group and the simple magnetic radiation group. Compared with the control group and the spiking group, the MFH groups showed significant differences in apoptotic cells rate. The proportion of apoptotic cells was significantly increased with increased Fe<sub>2</sub>O<sub>3</sub> nanoparticle concentrations in the MFH groups (Figures 6 and 7).

### Immunocytochemical test results

**Staining criteria.** Hsp70 positive sites were concentrated in the cell membrane and cytoplasm as rings or patches of red or reddish-brown color. The nuclei were negative. Bax and Bcl-2 staining was mainly in the cytoplasm appearing as red or reddish-brown patches. p53 staining was mainly in the nucleus appearing as uniform red or red-brown particles. The morphology of the entire nucleus was clearly visible.

The cells adhering to a coverslip were deemed positive if the percentage of positive cells accounted for >10% of the tumor cells examined in 10 high-power fields

**Table 2.** MTT results of SMMC-7721 cells after MFH using Fe<sub>2</sub>O<sub>3</sub> nanoparticles.

Groups	ABS value	Cell survival rate (%)	Toxicity classification
Control group A	0.384 ± 0.027	100.00	0
Control group B	0.383 ± 0.026	99.74	1
Spiking group	0.376 ± 0.025	97.91	1
MFH group			
2 g/L Fe <sub>2</sub> O <sub>3</sub>	0.270 ± 0.037 <sup>a</sup>	70.31	2
4 g/L Fe <sub>2</sub> O <sub>3</sub>	0.266 ± 0.050 <sup>a</sup>	69.27	2
6 g/L Fe <sub>2</sub> O <sub>3</sub>	0.170 ± 0.040 <sup>a</sup>	44.27	3
8 g/L Fe <sub>2</sub> O <sub>3</sub>	0.070 ± 0.014 <sup>a</sup>	18.23	4

Data are reported as means ± SD. Control group A: RPMI 1640 culture medium only; Control group B: RPMI 1640 culture medium and radiation; spiking group: 8 g/L Fe<sub>2</sub>O<sub>3</sub>, no radiation; MFH: magnetic fluid hyperthermia. <sup>a</sup>P<0.05 compared with control group A, control group B, and spiking group (*t*-test).

selected in different regions. A total of 200 clearly distributed tumor cells were counted by two observers in a double-blind manner and the mean was calculated. The positive index (PI) values of each group were calculated as: PI=number of positive cells/number of total tumor cells × 100%.

#### Immunocytochemistry results for Hsp70

The cells of the control group A and the spiking group were barely stained, if at all. In contrast, the membrane and cytoplasm of the MFH group cells were visibly red or reddish-brown (Figure 8). The PI of the MFH group increased with rising ferrofluid concentration, suggesting that hyperthermia induced Hsp70 expression.

#### Immunocytochemistry results for p53

For the control group and the spiking group, a large number of tumor cells were stained red in the nucleus due to p53 expression. The nuclear morphology was clearly

visible and the color was light. For the MFH group, particulate red or reddish-brown staining areas could be observed in the nucleus of the tumor cells. The number of positively stained cells and the staining intensity were negatively correlated with the ferrofluid concentration (Figure 9). The deposition of brown magnetic nanoparticles could be noted in intracellular and intercellular zones (Figure 10).

#### Immunocytochemistry results for Bax and Bcl-2

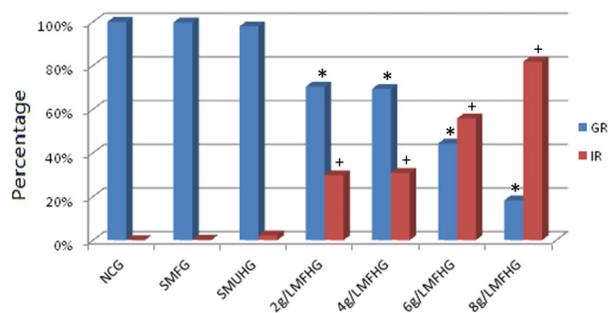

In the control group A, Bax and Bcl-2 had different levels of expression. Specifically, particulate red-stained areas were visible in the cytoplasm whereas no obvious staining reaction was observed in the nucleus. The spiking group was largely identical to the control group A. In the MFH group, increasing the ferrofluid concentration significantly enhanced Bax expression while Bcl-2 expression changed little, and the staining was relatively light. Deposition of brownish magnetic nanoparticles could be noted both inside and outside the tumor cells (Figures 11 and 12). The ratio of Bax/Bcl-2 appeared to increase with rising ferrofluid concentration.

#### RT-PCR results for Hsp70

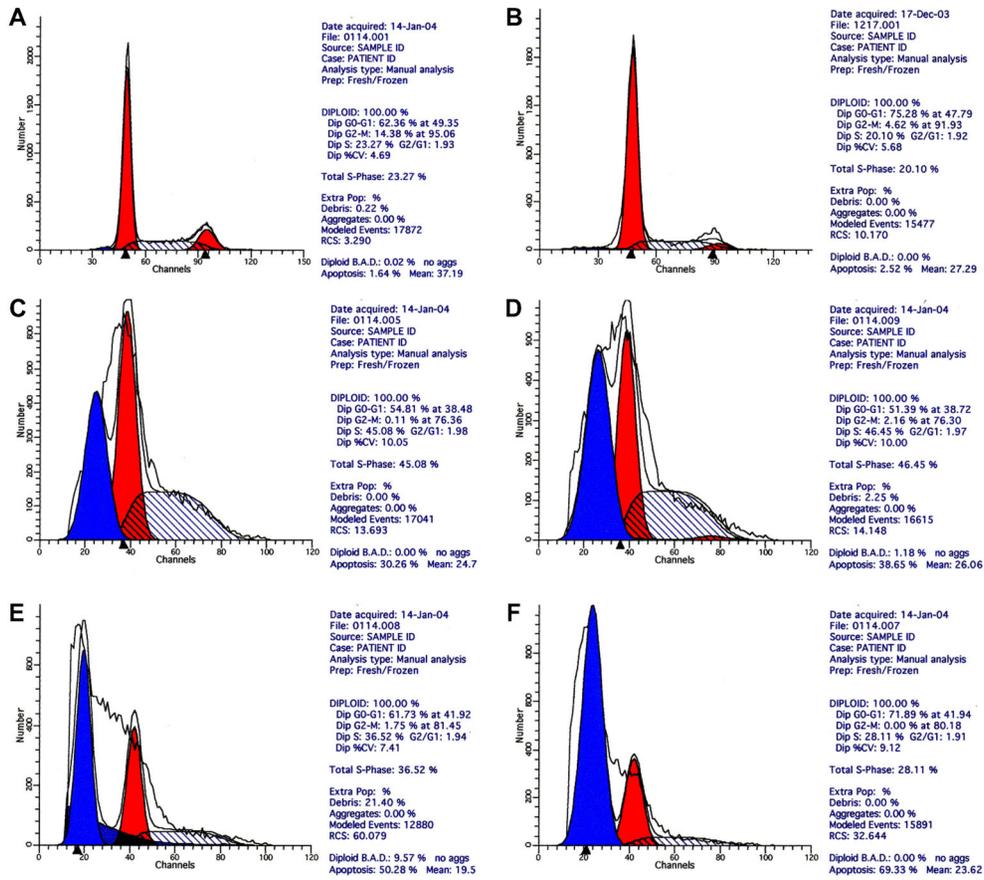

**RNA concentration and purity.** The A<sub>260</sub> and A<sub>280</sub> values of the RNA samples were measured and the ratios for all samples were found to be greater than 1.8, which met the requirement for RNA extraction. The presence of three complete strips (5S, 18S, 28S) following electrophoresis confirmed the RNA integrity (Figure 13).

#### Electrophoresis

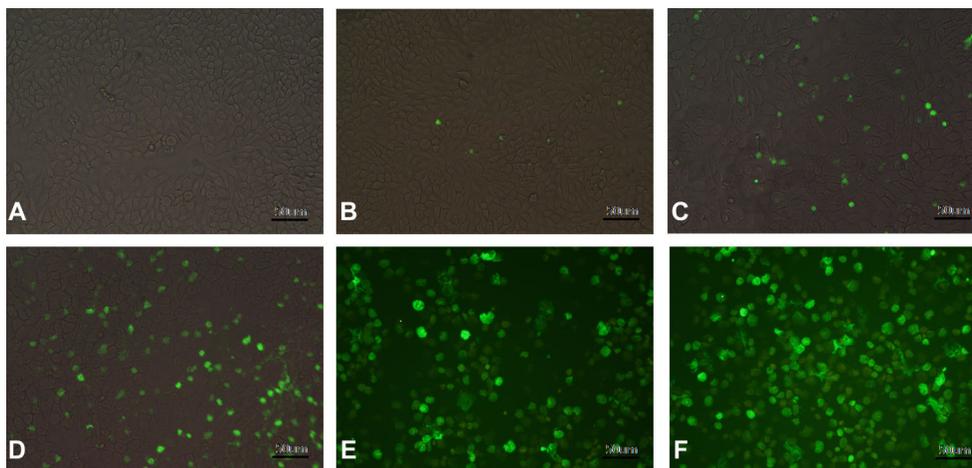

After hyperthermia treatment for 8-12 h, electrophoresis results showed that Hsp70 and β-actin strips were not observed in control group A, the cells of the spiking group did not express Hsp70 but did express β-actin, and the target fragment was 240 bp in size. For control group B, target fragments appeared at 240 and 348 bp, corresponding to β-actin and Hsp70, respectively. The electrophoresis

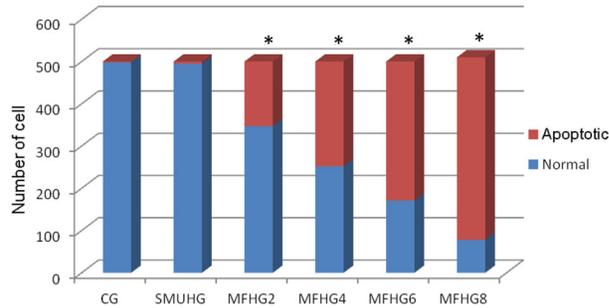

**Figure 4.** MTT histogram of SMMC-7721 cells after treatment. MFH: magnetic fluid hyperthermia.

**Figure 7.** Apoptosis rates of treatment groups. CG: control group, SMUHG: spiking group (8 g/L  $\text{Fe}_2\text{O}_3$ , no radiation), MFHG: magnetic fluid hyperthermia groups with 2, 4, 6, and 8 g/L  $\text{Fe}_2\text{O}_3$ . \* $P < 0.05$  compared with control and spiking group (*t*-test).

images of the MFH group showed both  $\beta$ -actin and Hsp70 strips at 240 and 348 bp. The Hsp70 strip of the MFH group with 6 g/L  $\text{Fe}_2\text{O}_3$  nanoparticle ferrofluid was the brightest (Figure 14A).

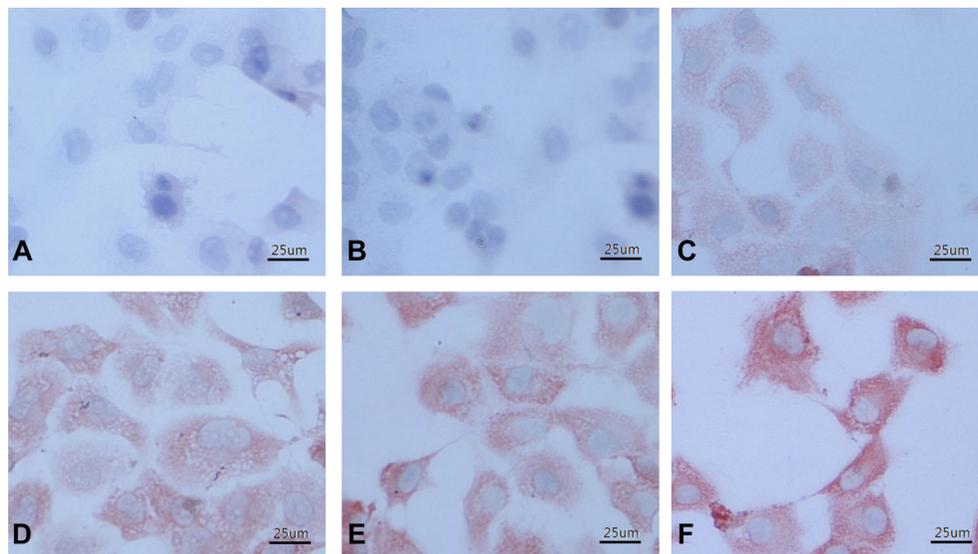

After hyperthermia treatment for 24 h, there were no Hsp70 and  $\beta$ -actin strips in the control group A electrophoresis lane, the spiking group did not express Hsp70, but did express  $\beta$ -actin, and the target fragment was 240 bp in size. For the control group B, target fragments appeared at 240 and 348 bp, corresponding to  $\beta$ -actin and Hsp70, respectively. The electrophoresis images of the MFH group were similar to those of the control group A and the spiking group with no strip at 348 bp (Figure 14B), indicating that after hyperthermia for 24 h, the expressed proteins were degraded or Hsp70 expression was inhibited.

## Discussion

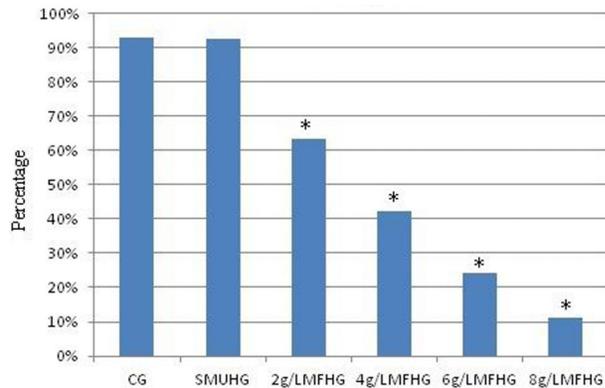

### Effect of MFH on SMMC-7721 cells

The tumor cells could load a significant amount of superparamagnetic  $\text{Fe}_2\text{O}_3$  nanoparticles, and the daughter cells received 50% of the magnetic particles during cell division. Hence, not only the tumor cells but also their daughter cells were susceptible to the alternating magnetic field irradiation and both exhibited a high death rate (23). We found that  $\text{Fe}_2\text{O}_3$  nanoparticles could enter into the cytoplasm and lysosomes of the SMMC-7721 cells. The  $\text{Fe}_2\text{O}_3$  nanoparticles could efficiently convert the energy of the high-frequency alternating magnetic field (200 kHz, 4 kW, output current 300 A) into heat. When the ferrofluid was diluted with 0.9% NaCl to concentrations of 2, 4, 6, or 8 g/L and then heated for 60 min in high-frequency alternating magnetic field (output current 300 A), the temperature rose to 39–54°C. Note that after heating for 40 min, the ferrofluid temperature no longer increased but remained at a constant level. Hence, the  $\text{Fe}_2\text{O}_3$  nanoparticle ferrofluid can be a relatively noninvasive means to treat tumors with constant-temperature hyperthermia.

Electron microscopy, MTT assay and flow cytometry analysis showed that after MFH treatment, there were notable changes in the apoptotic SMMC-7721 cells, such as chromatin condensation, formation of crescent bodies, fragmentation of nuclei, and cell shrinkage. In addition, MFH induced SMMC-7721 cell apoptosis in a dose-dependent manner, and the maximum apoptosis rate reached 69.33%. Compared with control group cells, the MFH cells exhibited a notable hypodiploid peak ahead of

**Figure 8.** Immunochemical images (400 $\times$ ) of Hsp70 expression in SMMC-7721 hepatoma cells. MFH: magnetic fluid hyperthermia.

**Figure 9.** p53 histogram of SMMC-7721 cells after treatment. CG: control group A; SMUHG: spiking group (8 g/L Fe<sub>2</sub>O<sub>3</sub>, no radiation); MFHG: MFH group; PI: positive index. \*P<0.05 compared with CG (*t*-test).

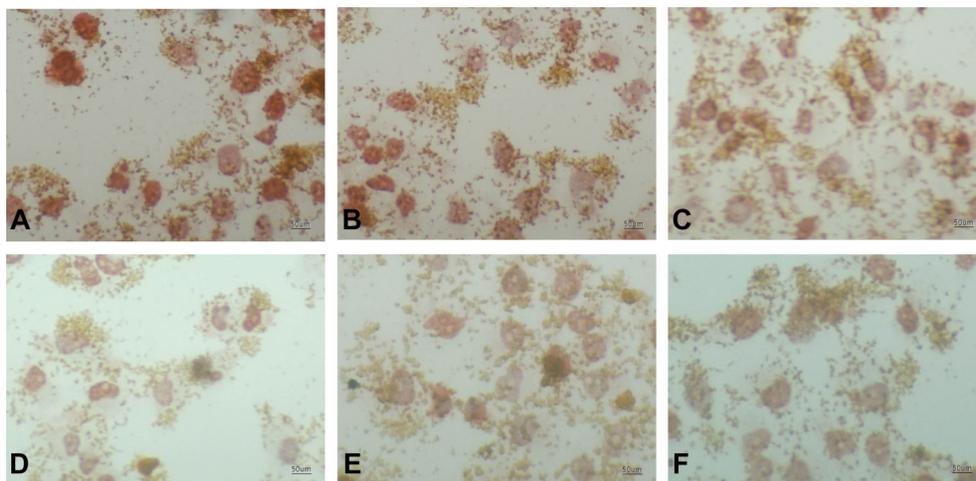

the G1 peak. The cell cycle thus appeared to be arrested at the G2/M phase (24). Yuguchi also observed that hyperthermia could arrest the cell cycle at the G0/G1 phase (25). The MTT results showed that Fe<sub>2</sub>O<sub>3</sub> nanoparticle ferrofluid hyperthermia inhibited the proliferation of SMMC-7721 cells. The inhibition rate increased with rising ferrofluid concentration and reached a maximum of 81.2%.

#### Effect of MFH on hepatocarcinoma-related genes and proteins

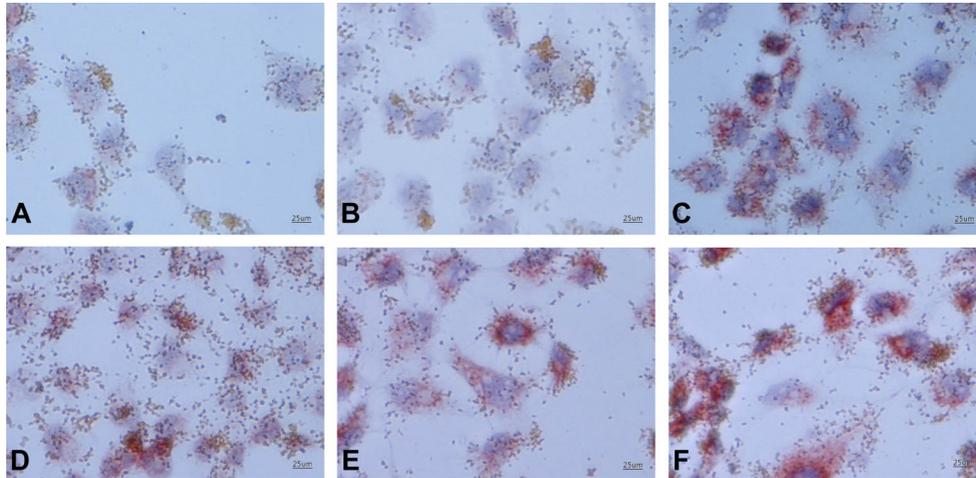

Immunocytochemical staining showed that the tumor cells in the control group expressed Bax and Bcl-2 to various extents, as demonstrated by the particulate red staining zones in the cytoplasm; the nucleus showed no

obvious coloration. The tumor cells of the spiking group appeared largely identical to those of the control group. In the MFH group, the Bax expression was enhanced remarkably with rising ferrofluid concentration, whereas the Bcl-2 expression changed little and the staining reaction was relatively light. Deposition of brown nanoparticles was visible both inside and outside the tumor cells. In addition, the Bax/Bcl-2 ratio appeared to increase with rising ferrofluid concentration, suggesting that MFH could induce high Bax expression and exercise an antitumor effect by altering the Bax/Bcl-2 ratio. This is in agreement with Zhang (26) (24), who argued that *Bcl-2* and *Bax* constitute a pair of positive and negative regulators. Their proteins are both homogeneous dimers, and during reaction one molecule of Bcl-2 and one molecule of Bax are needed to combine into a heterodimer. The Bax/Bcl-2 ratio plays a key role in determining cell survival upon stimulation. Overexpression of Bcl-2 (Bcl-2-Bcl-2) leads to cell survival whereas overexpression of Bax (Bax-Bax) causes cell death. Bian et al. (27) also reported that the expression of Bcl-2 in tumor cells decreased significantly after hyperthermia treatment whereas Bax expression was strongly enhanced. Tumor necrosis was not observed during cancer regression. Thus, it can be considered that hyperthermia can be used clinically to kill tumor cells through apoptosis.

It has also been reported that treating malignant fibrous histiocytoma MFH-2NR cells at 43°C for 1 h led to morphological changes indicative of apoptosis. The expression of *Bax* mRNA increased significantly and peaked after 30 min of heating, and the increased Bax expression was realized through the specific p53-independent pathway (28). Immunocytochemistry studies showed that in the control group and the spiking group,

A, Control group A (RPMI 1640 culture medium only); B, spiking group (8 g/L Fe<sub>2</sub>O<sub>3</sub>, no radiation); C, 2 g/L Fe<sub>2</sub>O<sub>3</sub> MFH group; D, 4 g/L Fe<sub>2</sub>O<sub>3</sub> MFH group; E, 6 g/L Fe<sub>2</sub>O<sub>3</sub> MFH group; F, 8 g/L Fe<sub>2</sub>O<sub>3</sub> MFH group. MFH: magnetic fluid hyperthermia.

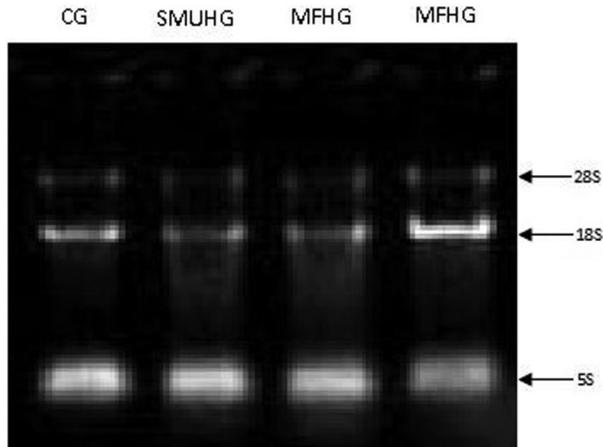

**Figure 11.** Immunocytochemical images (400 ×) of Bax expression in SMMC-7721 hepatoma cells. A, Control group A (RPMI 1640 culture medium only); B, spiking group (8 g/L  $\text{Fe}_2\text{O}_3$ , no radiation); C, 2 g/L  $\text{Fe}_2\text{O}_3$  MFH group; D, 4 g/L  $\text{Fe}_2\text{O}_3$  MFH group; E, 6 g/L  $\text{Fe}_2\text{O}_3$  MFH group; F, 8 g/L  $\text{Fe}_2\text{O}_3$  MFH group. MFH: magnetic fluid hyperthermia.

the tumor cells nuclei readily expressed p53, which was stained red. The nucleus showed clear morphology with light staining color. In contrast, particulate red or reddish-brown stained areas could be seen in the nuclei of tumor cells in the MFH group. The number of positively stained cells and the staining intensity were negatively correlated with the ferrofluid concentration. The deposition of brown magnetic nanoparticles could be noted in intracellular and intercellular zones. Hyperthermia was found to increasingly inhibit mutant p53 expression with rising ferrofluid concentration. Low expression of mutant p53 resulted in relatively high expression of wild-type p53, which initiated a variety of proapoptotic pathways and promoted the

antitumor effect. In addition, Matsumoto et al. (29) argued that heating can also stimulate the expression of wild-type p53 and suggested that hyperthermia-induced apoptosis is regulated by the p53 gene. Ohnishi et al. (30) suggested that P21/WAF1/CIP1 protein, which is the product of the oncogene *k-ras*, is an inhibitor of the cyclin D kinase (CDK) that can be activated by p53 at the transcription level to inhibit the progression of G1/S phase cells and promote apoptosis. Heating can induce the expression of tumor necrosis factor (TNF)- $\alpha$  and promote apoptosis. Thus, hyperthermia mainly induces the expression of wild-type p53, inhibits the expression of mutant p53, increases the ratio of wild-type/mutant p53 proteins, and promotes the

CG: control group A (RPMI 1640 culture medium only); SMUHG: spiking group (8 g/L Fe<sub>2</sub>O<sub>3</sub>, no radiation); MFHG: magnetic fluid hyperthermia group (lane 3: 2 g/L Fe<sub>2</sub>O<sub>3</sub>; lane 4: 8 g/L Fe<sub>2</sub>O<sub>3</sub>).

apoptosis of SMMC-7721 cells through a series of proapoptotic pathways.

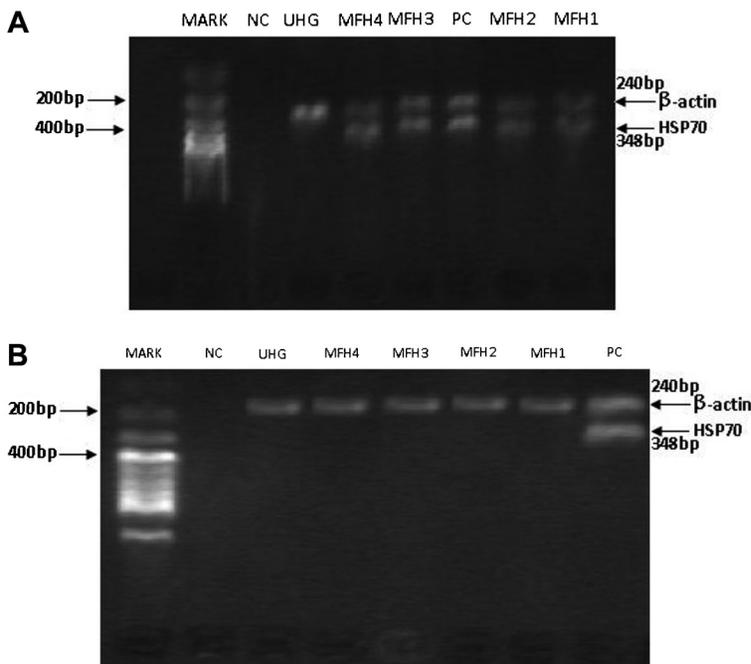

The so-called thermal tolerance phenomenon can be experienced in hyperthermia, where more repetitions of treatment appear to deteriorate the efficacy. It has been suggested that the thermal tolerance of tumor cells is

associated with the Hsp family (31,32). The expression of Hsp70 protein and mRNA of SMMC-7721 cells after MFH treatment was examined by immunocytochemistry and RT-PCR. It was found that the expression of both Hsp70 protein and mRNA increased after 8 h and peaked after 12 h of MFH treatment, and no expression was observed after 24 h. The results indicate that Hsp70 is relevant to the thermal tolerance in the early stage of the MFH treatment, but has little influence on the apoptosis.

Therefore, in this study, the therapeutic effect of Fe<sub>2</sub>O<sub>3</sub> nanoparticle ferrofluid on SMMC-7721 cells in hyperthermia treatment was mainly due to increased Bax/Bcl-2 ratio and increased wild-type/mutant p53 protein ratio, which promoted the apoptosis of hepatoma cells. Hsp70 has relatively little direct effect of tumor cell apoptosis in the hyperthermia treatment. Hsp70 may be responsible for the thermal tolerance observed in the early stage of hyperthermia and for part of the antitumor immunity.
