Abstract

Objective: Mitral valve repair in rheumatic patients is still a challenge. The aim of this study is to assess the results of mitral valve repair in rheumatic patients with rheumatic mitral insufficiency.

Methods: 330 patients with rheumatic mitral insufficiency who had undergone mitral valve repair in the Heart Institute HC-FMUSP were assessed retrospectively, between 1985 and 2005. The mean age was 26.9 ± 15.4 years and 57.6% were female. On preoperative assessment, 39.5% of patients were in NYHA functional class IV. The most common techniques for repair employed were bovine pericardial strip annuloplasty in 48.4% patients and Carpentier ring annuloplasty in 22.6%. Shortening of chordae (20%) and papillary muscle splitting (17.8%) were the most common associated techniques performed. Tricuspid valve repair (26.7%) and aortic valve replacement (27.2%) were the most common associated procedures.

Results: The hospital mortality was 0.9% (three patients), two of them children with active rheumatic fever. Linearized rates of thromboembolism, endocarditis, reoperation and late death were 0.2%, 0.2%, 3.5% and 0.5% patients-year, respectively. Actuarial survival in 20 years was $86.4 \pm 6.6\%$.

Freedom from reoperation in 20 years was $30.3 \pm 11.1\%$.

Conclusion: Mitral valve repair in rheumatic patients is a feasible procedure in correction of mitral insufficiency with low operative mortality.

Descriptors: Mitral valve/surgery. Mitral valve insufficiency/surgery. Rheumatic fever.

Resumo

Objetivo: A plástica da valva mitral em pacientes reumáticos permanece um desafio. O objetivo deste estudo é analisar a técnica e os resultados da plástica da valva mitral em pacientes com insuficiência mitral reumática.

Métodos: Foram analisados, retrospectivamente, 330 pacientes portadores de insuficiência mitral reumática submetidos à plástica da valva mitral no Instituto do Coração do HC-FMUSP, entre 1985 e 2005. A idade média foi de $26,9 \pm 15,4$ anos e 57,6% dos pacientes eram do sexo feminino. No pré-operatório, 39,5% dos pacientes estavam em classe funcional IV. As técnicas de plástica mais comumente utilizadas foram a anuloplastia posterior com tira de pericárdio bovino em 48,4% dos pacientes e a anuloplastia com anel de Carpentier em 22,6%. As técnicas associadas

Article received on February 20th, 2009

Article accepted on August 31th, 2009

foram empregadas em 55,2% dos pacientes, sendo as mais comuns: encurtamento de cordas (20%) e papilarotomias múltiplas (17,8%). Plástica da valva tricúspide (26,7%) e substituição da valva aórtica (27,2%) foram os procedimentos associados mais frequentes.

Resultados: A mortalidade hospitalar foi 0,9% (três pacientes), sendo dois deles crianças em atividade reumática. As taxas linearizadas de tromboembolismo, endocardite, reoperação e óbito tardio foram de 0,2%, 0,2%, 3,5% e 0,5%

pacientes-ano, respectivamente. A sobrevida actuarial foi de $86,4 \pm 6,6\%$ em 20 anos. A curva livre de reoperação foi de $30,3 \pm 11,1\%$ em 20 anos.

Conclusões: A plástica da valva mitral em pacientes reumáticos é uma técnica factível na correção da insuficiência mitral, com baixa mortalidade operatória.

Descritores: Valva mitral/cirurgia. Insuficiência da valva mitral/cirurgia. Febre reumática.

INTRODUCTION

The techniques of mitral valve repair are procedures of choice in the surgical treatment of mitral valve disease, and are increasingly used in the surgical management of valvular diseases and preferable to valve replacement when technically feasible.

Knowledge of three-dimensional mitral valve anatomy and its work during the cardiac cycle, associated to the understanding of the mechanisms contributing to the valve dysfunction is critical to the success of the conservative mitral valve surgery.

Until now we could not find uniform results in the literature of mitral valve repair in patients with lesions resulting from rheumatic fever [1-3]. The explanation could be related to the interference of new rheumatic outbreaks in these patients. However, there is agreement on the lowest morbidity and mortality of patients undergoing mitral valve repair compared with valve replacement.

This study aims to analyze the 20-year late results of mitral valve repair in rheumatic patients, using various repair techniques.

METHODS

During the period from January 1985 to December 2005, 330 patients with rheumatic fever diagnosed with mitral failure underwent mitral valve repair at the Heart Institute of the Clinics Hospital of the Faculty of Medicine, University of São Paulo. The study was approved by the Scientific Committee of the Heart Institute and the Ethics Committee of the Clinics Hospital of the Faculty of Medicine, University of São Paulo.

The patients' ages ranged from 5 to 57 years, mean 26.9 ± 15.4 years. One hundred and ninety (57.6%) patients were female and 140 (42.4%) were male.

The techniques of mitral valve repair were: posterior annuloplasty using bovine pericardial patch in 160 (48.4%), Carpentier ring in 75 (22.6%), posterior segmental annuloplasty in 32 (9.7%), quadrangular resection of the posterior leaflet with plication of the ring in 23 (6.9%),

posterior Shore annuloplasty in 12 (3.6%), triangular resection of the anterior leaflet in eight (2.4%), Kay in five (1.5%), enlargement of the posterior leaflet using bovine pericardium in four (1.2%), double-U as opposed in four (1.2%), Reed in three (0.9%), cleft suturing in two (0.6%) and Puig-Massana ring in one (0.3%). Associated techniques were used in 182 (55.2%) patients, and the most frequent was cords shortening in 66 (20%) cases. Other techniques used were: multiple papillectomy in 59 (17.8%) cases, commissurotomy in 30 (9.1%), smoothing of the posterior leaflet in eight (2.4%), resection of short strings in three (0.9%), cusp repair in three (0.9%), papillary muscle sliding in two (0.6%) and transposition of chords in one (0.3%).

Associated operations were performed in 219 (66.4%) patients, 90 (27.2%) aortic valve replacements, 88 (26.7%) tricuspid valve repair, 23 (7%) aortic valve repair, 10 (3%) aortic commissurotomies, six (1.8%) CABG and two (0.6%) tricuspid valve replacements.

Regarding the functional class (New York Heart Association), 130 (39.5%) patients were in functional class IV, 179 (54.3%) in functional class III and 21 (6.2%) in functional class II.

The postoperative follow-up was performed through hospital consultations or telephone interviews or using questionnaires sent by mail.

Data will be presented in accordance with the revised standards for data reporting and nomenclature. The survival actuarial and free from events were calculated using the Kaplan Meier [4] and compared by linear regression analysis. The linearized rates of events are expressed as a percentage of events per patient/year (%/pat.-year).

RESULTS

The hospital mortality was 0.9% (three patients). The causes were low cardiac output in two (0.6%) patients - one was a child who was under rheumatic activity - and multiple organ failure in one (0.3%) patient - with also a child under rheumatic activity.

In the late postoperative period, 177 (63%) patients were

in functional class I, 51 (18.1%) were class II, 37 (13.2%) were in functional class III and 16 (5.7%) patients in functional class IV. The period of follow-up was 17,486 months/patients (88.3% full).

Late mortality in this population was 2.8% (nine patients). Five patients died due to heart failure, two, sepsis and the other two the cause of death was unknown.

The linearized rates of the events reoperation, death, endocarditis, and thromboembolism are shown in Table 1. There was no hemolysis in this series of patients.

The actuarial survival in 20 years was $86.4 \pm 6.6\%$ (Figure 1). The actuarial curves free from thromboembolism (Figure 2), reoperation (Figure 3) and endocarditis (Figure 4) were $99.7 \pm 0.3\%$, $30.3 \pm 11.1\%$ and $95.6 \pm 4.3\%$ in 20 years, respectively.

Table 1. Linearized rates of the events (late evolution).

Event	% patients-year
Reoperation	3.5
Death	0.5
Endocarditis	0.2
Thromboembolism	0.2

Fig. 1 - Actuarial survival at 20 years

Fig. 3 - Actuarial curve free from reoperation

Fig. 4 - Actuarial curve free from endocarditis

DISCUSSION

A degenerative disease of the mitral valve is the most common cause of mitral failure in industrialized countries. In such cases, the mitral valve repair is the procedure of choice, with excellent late results [5,6]. However, in our country, rheumatic etiology is prevalent and, in this population, the long-term outcomes may be affected by the appearance of new outbreaks of the disease [7]. Despite this fact, every effort must be made in order to perform conservative treatment, since a large proportion of these patients are young and therefore subject to greater number of surgical interventions during evolution [8,9]. Other factors to be considered are the difficulty of anticoagulation of patients in our country and early calcification of bioprostheses in this age group.

Mitral valve repair in rheumatic patients have shown better outcomes than mitral valve replacement [10]. On the other hand, conservative surgery of the mitral valve in rheumatic patients is technically more difficult than in patients with degenerative valvular heart disease [11] and its outcomes depend on the degree of impairment of the valve at the time of surgical approach, that is, the worse the conditions at the time of reconstruction, the worse the outcome [12,13].

The valve repair requires the surgeon a perfect knowledge of anatomy and the multiplicity of existing techniques. Moreover, the evaluation of the leaflets, the subvalvular plane, the tendinae cords and papillary muscles should be performed in a systematic manner during surgery. The test with saline solution complements this analysis. Transesophageal Doppler echocardiography has contributed to the evaluation and intraoperative decision.

The choice of technique to be used for annuloplasty should take into account the valve change. Usually, the dilation of the mitral orifice affects only the posterior two thirds of the annulus, which corresponds to the area of the posterior leaflet. Several rings have been described, rigid or flexible, to remodel the mitral valve [2,14]. Loop et al. [15] prefer the use of the Carpentier ring to reduce the annulus. Although widely used, the rigid rings may have some problems, such as systolic anterior motion in 4% to 10% of cases, causing obstruction of the outflow tract of the left ventricle [16]. In our Service, we have used this technique preferably in the large dilated left ventricle and, in other situations where it is necessary to reduce the annulus, we used a bovine pericardium patch from trigone to trigone, with good late outcomes [17]. A bovine pericardium patch is flexible and does not interfere with the normal anatomy of the mitral annulus, which we now know is not flat and is changed during the different phases of the cardiac cycle.

However, other authors have used grafts from autologous tissue, such as the posterior leaflet of the tricuspid valve [18] and pericardium [19], in mitral valve repair in rheumatic patients, on which the shrinkage and low mobility are the primary findings.

The late results of mitral valve repair also depend on a good coaptation of the leaflets, that is, an area of adequate coaptation after valve repair. This good coaptation can be achieved with the help of the shortening of the chordae tendinae [20] or shortening of papillary muscles. Recently, in children, we have increased the use of sliding of both papillary muscles in order to proceed to the shortening of all the cords of the anterior leaflet.

The hospital mortality was 0.9%, a low value when compared to international literature, which ranges from 2.6% to 3.6% [2,21]. In our country, Petrucci Jr et al. [22] reached a mortality rate of 0% in a small group of 23 rheumatic patients undergoing mitral valve repair. The late mortality of 3.2% with linear rate of 0.5% patient/years was also lower than that found in the literature [11,21].

The linearized rate of reoperation found of 3.5% patients-years was similar to the literature [11] and higher when compared to patients with degenerative etiology [23]. A higher linearized rate of reoperation is expected, since the rheumatic etiology is a risk factor for reoperation due to outbreaks of rheumatic fever, which continually provoke structural changes in the mitral valve apparatus [24].

The rheumatic patients undergoing mitral valve repair showed low rates of complications (thromboembolism, endocarditis, and hemolysis) in the long-term. Such outcomes are similar to those found in the literature [11,25].

CONCLUSION

In conclusion, mitral valve repair is feasible in the correction of mitral failure of rheumatic etiology, with low operative mortality.
