Denise Falcke<sup>3</sup> 

**Abstract:** Intimate partner violence may be influenced by family experience. This study aims to test a dyadic model verifying the relationship between events experienced in the family of origin and intimate partner violence. This study addressed 304 heterosexual couples using a sociodemographic questionnaire, the Revised Conflict Tactics Scales (CTS2), and Family Background Questionnaire (FBQ). The analyses were performed using the actor-partner interdependence model (APIM) and the structural equation model. Less intense violence was positively and significantly correlated with violence perpetrated by husbands and wives ( $r = 0.661$ ;  $p < 0.01$ ), whereas no correlation was found between severe violence and latent factors, excluding interdependence between the dyads. All the seven models presented satisfactory goodness of fit (CFI > 0.91; RMSEA < 0.08), except for the dimension “sexual abuse”. Therefore, the results reinforce that the events experienced in the family of origin influence intimate partner violence.

**Keywords:** family of origin, marital conflict, family violence

## Experiências na Família de Origem e Violência Conjugal: Análise do Modelo Diádico

**Resumo:** A violência conjugal pode ser influenciada pela vivência familiar. Este estudo objetivou testar um modelo diádico de relação entre as experiências na família de origem e a violência conjugal. Realizou-se investigação com 304 casais heterossexuais com base em questionário de dados sociodemográficos, no *Revised Conflict Tactics Scales* (CTS2) e no *Family Background Questionnaire* (FBQ). As análises foram realizadas utilizando-se o modelo de interdependência ator-parceiro (APIM) por meio de equações estruturais. A violência de menor intensidade correlacionou-se positiva e significativamente entre a violência cometida pelos maridos e pelas esposas ( $r = 0,661$ ;  $p < 0,01$ ). Já a violência grave não foi correlacionada significativamente entre os fatores latentes, excluindo a interdependência entre a díade. Entre os sete modelos testados, todos apresentaram bons índices de ajuste (CFI > 0,91; RMSEA < 0,08), exceto a dimensão “abuso sexual”. Assim, reforça-se que as experiências vivenciadas na família estão relacionadas à violência conjugal.

**Palavras-chave:** família de origem, conflito conjugal, violência na família

## Experiencias Familiares de Origen y Violencia Conyugal: Análisis de un Modelo Diádico

**Resumen:** La violencia conyugal puede verse influida por la experiencia familiar. Este estudio tiene como objetivo probar un modelo diádico de la relación entre las experiencias en la familia de origen y la violencia conyugal. Se llevó a cabo una investigación con 304 parejas heterossexuales, utilizando un cuestionario sociodemográfico, *Revised Conflict Tactics Scales* (CTS2) y *Family Background Questionnaire* (FBQ). Los análisis se realizaron utilizando el modelo de interdependencia actor-socio (APIM) utilizando ecuaciones estructurales. La violencia menos intensa se correlacionó positiva y significativamente entre la violencia cometida por maridos y esposas ( $r = 0,661$ ;  $p < 0,01$ ), mientras que en la violencia severa no hubo correlación significativa entre los factores latentes, excluyendo interdependencia entre la díada. Entre los siete modelos probados, todos mostraron buenas tasas de ajuste (CFI > 0,91; RMSEA < 0,08), excepto por la dimensión “abuso sexual”. Así, se refuerza que las experiencias vividas en la familia están relacionadas con la violencia conyugal.

**Palabras clave:** familia de origen, conflicto marital, violencia doméstica

Intimate partner violence has been more intensively studied since the 1970s and has raised the attention of researchers in many countries (Hardesty & Ogolsky, 2020). It is defined as physical, sexual and/or psychological abused perpetrated by at least one of the partners (Martins, Rato, & Marques, 2018). Even though these forms of violence is commonly addressed by researchers, Straus, Hamby, Boney-McCoy and Sugarman (1996) consider physical injury to be different from physical assault, highlighting

the consequences of violent acts, such as sprains, bruises, and fainting, for instance.

Intimate partner violence is usually associated with, and often explained by, gender issues and based on the social construction of unequal power between men and women (Brancaglioni & Fonseca, 2016). Hence, this analysis still considers women to be fragile (Rodrigues, Machado, Santos, Santos, & Diniz, 2016). Another perspective considers there is a relational bias in domestic violence. Bates, Graham-Kevan and Archer (2014) addressed 706 women and 398 men and did not find substantial differences in violent behavior when considering gender and the context in which aggression took place.

It does not mean that in specific violent contexts, victims and aggressors cannot be identified, considering that men and women interact in complex social, cultural, and familial contexts, demanding individualized assessments. Hence, the spouses' different experiences of violence, including their families of origin, tend to influence relationships established in adulthood, especially marital relationships (Brennan, Borgman, Watts, Wilson, & Swartout, 2020; Madalena, Carvalho, & Falcke, 2018). Repeated behaviors may be associated with the transgenerational concept, which is seen as a set of behavioral and relational models transmitted from a generation to another. These family models can influence new relationships individuals establish throughout life (Camicia, Silva, & Schmidt, 2016).

Tondowski et al. (2014) verified that violence-related family patterns are recurrent via intergenerational transmissions and manifest as physical or verbal aggression, in the form of crying or silence, throughout the different generations studied. The experiences within the family of origin that may affect the future relationships of children include: (a) physical violence perpetrated by the parents/caregivers during childhood (Barros & Freitas, 2015); (b) the parents' psychological maladjustment such as the presence of emotional problems (Bouvette-Turcot, Bernier, & Leblanc, 2017); (c) parenting styles, especially physical neglect (De Antoni & Batista, 2014); (d) parental alliance, which refers to the relationship between parents regarding the upbringing of children or even potential situations of violence between the couple (J. M. M. Silva, Lima, & Ludermir, 2017).

Fehringer and Hindin (2009) investigated these relational and transgenerational patterns in the Philippines and highlighted the role of witnessing violence and intimate partner violence during childhood. Having witnessed

physical violence between parents during childhood predicted intimate partner violence among 472 participants. In Brazil, 10 couples reported that the choice of a spouse went through the selection of individuals who consumed alcohol, which enabled that their family history would be repeated (Feijó et al., 2016). The use of alcohol, violence perpetrated by parents, helplessness, and loss of loved ones were common among the 10 mothers who used to assault their children (D.I. Silva, Maftum, & Mazza, 2014).

Scientific evidence suggests that violence can perpetuate for generations within the same family. However, the literature lacks investigations considering dyadic interactions (De Andrade, Cassepp-Borges, Ferrer, & Sanchez-Aragón, 2017), especially in the context of intimate partner violence (Razera, Gaspodini, & Falcke, 2017). There are dynamics in which an interdependent relationship is established between couples so that dyadic analyses have the advantage of providing a deeper understanding of the phenomenon under study (De Andrade et al., 2017). Because this is a complex phenomenon, this study aimed to test a dyadic model of the relationship between the events experienced within the family of origin and intimate partner violence.

## Method

A quantitative, descriptive and explanatory study was conducted. An explanatory study is intended to deepen knowledge concerning a given context and explains the occurrence of the phenomenon under study (Hernández Sampieri, Fernández Collado, & Baptista Lucio, 2013).

### Participants

A total of 304 heterosexual couples, 18+ years old, officially married or in a stable union for at least six months participate in this study. A convenience sample was recruited through snowball sampling (Biernacki & Waldorf, 1981). The inclusion criteria were being 18+ years old and having cohabited for at least six months.

Regarding their marital situation, 169 couples (55.6%) were officially married, and 135 (44.4%) were in a stable union. The women were aged 37.72 on average ( $SD = 12.55$ ), and men were aged 40.01 ( $SD = 12.75$ ). The duration of the relationships ranged from one to 56 years ( $M = 14.30$ ;  $SD = 11.09$ ). Table 1 presents other characteristics of the sample, not including missing data.

Table 1  
*Sample's sociodemographic characteristics*

Characteristics		Men		Women	
		N	%	N	%
One of the spouses were previously married	Yes	66	21.7	49	16.1
	No	236	77.6	253	83.2

Paid job	Yes	266	87.5	245	80.6
	No	37	12.2	54	17.8

## Instruments

*Sociodemographic questionnaire.* A form composed of 19 questions addressing the participants' characteristics and their relationships, such as gender and age, among others.

*Revised conflict tactics scales (CTS2).* This scale was developed by Straus et al. (1996) and adapted to Portuguese by Moraes, Hasselmann and Reichenheim (2002). It assesses violence in marital relationships and is composed of 78 questions addressing the actions of the respondents and their partners, distributed into five subscales: negotiation, psychological aggression, physical assault, injury, and sexual coercion, subdivided into minor and severe considering the intensity of acts.

The following subscales were used in this study: (1) Physical assault: minor – pushing, slapping, or twisting an arm; severe – punching, kicking, throwing against a wall, using a knife or firearm; (2) Psychological aggression: minor – insulting, swearing, or turning the back in the middle of a fight; severe – insults such as calling the person ugly, fat, or “bad in bed”; (3) Sexual coercion: minor – insistence in having sex, or oral or anal sex, without using physical force; Severe – same actions though using physical force or weapons to coerce the partner; (4) Injury: minor – bruises, purple spots, small cuts or pain; severe – requires medical assistance after a fight, fainting, or breaking bones.

The instrument is presented as a self-reported checklist (Moraes et al., 2002). The scale presented a Cronbach's alpha equal to 0.79 for perpetration and equal to 0.80 for victimization (Straus et al., 1996). Only data concerning the perpetration of violence were used in this study. The alpha for the women scale was 0.884 and for the men was 0.908, which is considered very good (Hernández Sampieri et al., 2013).

*Family background questionnaire (FBQ).* Self-reported instrument developed by Melchert (1998). It comprises 179 statements rated on a Likert scale, distributed on 22 subscales concerning the participants' memories of events experienced in their families of origin.

A total of 61 items were assessed in this study concerning the following subscales: (1) Parental physical abuse (father/mother) – physically violent behavior toward children; (2) Sexual abuse – any sexual act or game performed by parents, relatives, familiar or unfamiliar individuals. (3) Physical neglect – the parents do not provide physical care, for instance, food, hygiene, medical care, or clothing. (4) Substance abuse (father/mother) – parents' alcohol or drug abuse. (5) Psychological maladjustment (father/mother) – the parents present mental disorders such as psychopathologies, mood changes, or abuse of substances; (6) Parental alliance – level of agreement between parents concerning rules and guidance provided to children and whether there is violence in the parents' relationship.

One Brazilian study (Falcke, Wagner, & Mosmann, 2008) obtained reliability indexes equal to 0.99, which according to Hernández Sampieri et al. (2013), are very good parameters. The alpha obtained in this study for the full scale directed to women was 0.789 and 0.773 for the scale directed to men.

## Procedure

**Data collection.** Data were collected at the couples' homes or in places suggested by them. The authors simultaneously applied the instruments to the couple to ensure the independence of responses.

**Data analysis.** The analyses were based on the Actor-Partner Interdependence Model - APIM (Kenny, Kashy, & Cook, 2006), which considers the independence between individuals involved in dyadic relationships (couple); that is, each member of the pair directly or indirectly influence each other's emotions and behaviors as they share the same context and are exposed to similar influences (Cook & Kenny, 2005; Kenny et al., 2006). The method of dyadic analysis of data was based on Structural Equation Modeling - SEM, a multivariate technique used to analyze data that enables to empirically and simultaneously test a theoretical model

of multiple relations (Byrne, 2010), which is coherent to the complexity of psychological phenomena (Pilati & Laros, 2007). The models were assessed based on goodness of fit indexes. In addition to Chi-square Batista, Foguet and Coenders Gallart (2000) recommends Comparative Fit Index de Bentler – CFI Root Mean Square Error of Approximation - RMSEA. The analyses were performed with IBM SPSS® Amos™ 19.

### Ethical Considerations

This study was approved by the Institutional Review Board at the Universidade do Vale do Rio dos Sinos (CAAE No. 09/117, Protocol 11/129) and is in agreement with ethical guidelines regulating studies addressing human subjects, according to Resolution 510/2016, National Council of Health. The couples' participation was conditioned to them signing free and informed consent forms, and the participants' identities remained confidential.

## Results

Data were organized by gender in order to assess the heterosexual couples composing this study's sample. Note that the people in a dyad be ordered in an equivalent manner (Alferes & Kenny, 2009). Each individual in a dyadic model is matched with another person, and the pairs are measured by the same set of variables. Hence, the first analysis of dyadic data seeks to establish the extension to which both answers are correlated, that is, whether there is interdependence (also known as nonindependence) between the results. Non-independence can be used to infer reciprocity or influence and requires that data are analyzed to include the individuals and dyad as units of analysis (Kenny et al., 2006).

### Measuring nonindependence

The level of interdependence among the events experienced in the family of origin and intimate partner violence may occur due to factors associated with the fact these individuals are closely related and exposed to similar experiences (Cook & Kenny, 2005; Kenny et al., 2006). Nonindependence is determined by an association between the scores obtained by the members of a dyad. For couples with distinguishable members, as in this study, nonindependence can be measured using the Person's coefficient (Kenny et al., 2006). The correlations between the CTS2 and FBQ variables are presented in Table 2.

Table 2 shows that most of the dimensions are significantly correlated between the dyad members, indicating that the constructs are interdependent between the spouses. The CTS2's variables "severe physical assault" "paternal physical abuse" and FBQ's "sexual abuse" were not significantly correlated, and for this reason, not included in the Actor-Partner Interdependence Model (APIM).

Table 2

*Pearson's correlations between men and women for the CTS2 and FBQ variables*

CTS and FBQ Variables	Correlations
Minor Psychological aggression	.553**
Severe Psychological aggression	.178**
Minor injury	.424**
Severe injury	.222**
Minor Physical Violence	.373**
Severe Physical Violence	.074
Minor Sexual Coercion	.148*
Severe Sexual Coercion	.970**
Paternal physical abuse	.055
Maternal physical abuse	.132*
Sexual Abuse	-.043
Physical Neglect	.320**
Paternal Substance Abuse	.127*
Maternal Substance Abuse	.538**
Paternal Psychological Abuse	.156**
Maternal Psychological Abuse	.124*
Parental Alliance	.217**

\* $p < 0.05$ ; \*\* $p < 0.01$ .

### Confirmatory factor analysis with distinguishable dyads

The Confirmatory Factor Analyses (CFA) enable verifying the correlations between the dyads' latent variables and see whether there is nonindependence. To verify the correlations between latent variables, one has to analyze the factorial invariance of each scale in both groups to see whether the constructs have the same meaning in each group. In this study, the difference between the CFI ( $\Delta$ CFI) from one model to another should not be greater than 0.010. Therefore, the results indicate the feasibility of restricting factor loads to be the same in different groups (Milfont & Fischer, 2010). We tested the metric invariance of each scale with restricted and equalized factor loadings between the groups of the same structural model. The goodness of fit for the CFA for each scale is presented in Table 3.

The CTS-Minor and CTS-Severe final models, both the unrestricted model as the one with restricted factor loadings, presented satisfactory goodness of fit. Concerning minor violence perpetrated by men, the highest factor loading for "physical assault" was 0.890, and the lowest was 0.257 for "sexual coercion". The highest factor loading for women was 0.627 for "physical assault" and the lowest was 0.327 for "sexual coercion". Regarding men's severe violence, the highest loading was 0.962 for "injury" and the lowest was 0.563 for "psychological aggression". Among women, the highest load for severe violence was 0.364 for "physical assault" and the lowest was 0.10 for "psychological aggression".

The FBQ did not show satisfactory goodness of fit when the latent variables were included, even when applying suggested changes to the model. For this reason, the following analyses only included the dimensions observed, considering the sum of the items for each of the nine dimensions.

Once factor invariance was verified, the next step was determining the degree of correlation between the

pair's CTS latent variables, which meets the assumption of nonindependence. Regarding the CTS-minor, a positive and significant correlation was found between the violence perpetrated by men and women ( $r = 0.661; p < 0.01$ , Figure 1). The correlation between latent factors was not significant for the CTS-Severe, ( $r = 0.057; p = 0.352$ ), indicating no interdependence within the dyad. Therefore, APIM was performed with the CTS-Minor only.

Table 3  
Dyadic Confirmatory Factor Analysis for CTS2 and FBQ – Goodness of fit

Model	$\chi^2$	gl	p	CFI	RMSEA
CTS-Minor – unrestricted model	35.71	14	0.001	0.961	0.072
CTS- Minor – restricted factor loadings	40.86	17	0.001	0.957	0.068
CTS-Severe – unrestricted model	4.60	3	0.203	0.998	0.042
CTS-Severe – restricted factor loadings	5.58	5	0.348	0.999	0.020
FBQ – unrestricted model	555.44	129	0.01	0.714	0.104

**Actor-partner interdependence model (APIM)**

When using the Structural Equation Modeling (SEM), APIM enables simultaneously verifying the effects of individuals and partners on the study's dependent variable. Figure 1 presents APIM with the variables of violence-related experiences within the family of origin of men and women. There are two actor effects in this model, understood here as the effect of events the individual who perpetrates violence experienced in his/her family of origin: the first “female actor effect” is measured by the relationship between the events a woman experienced in her family of origin and the violence

she perpetrates. The second “male actor effect” is measured by the relationship between the events a man experienced in his family of origin and the violence he perpetrates.

Additionally, partner effects in the model suggest that an actor's experiences from his/her family of origin are related to the violence perpetrated by his/her partner. The first “female partner effect” is measured by the relationship between the events a woman experienced in her family of origin and the violence her partner perpetrates. The second “male partner effect” is measured by the relationship between the experiences of a man with his family of origin and the violence his partner perpetrates.

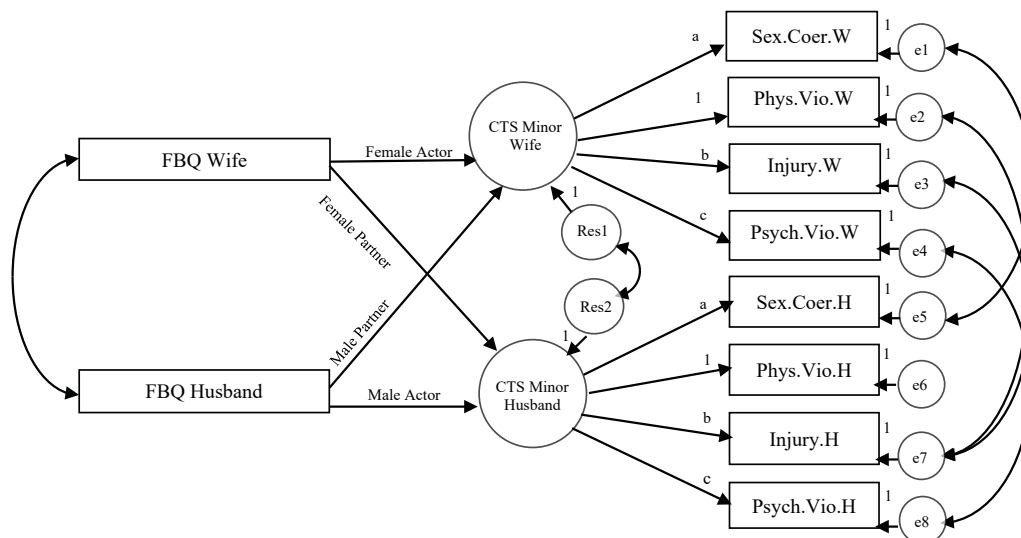

Figure 1. APIM – Relationship between the individuals' FBQ and CTS-Minor.

Seven models were estimated – one for each of the FBQ's dimensions (“paternal physical abuse” and “sexual abuse” were not tested because they did not meet the interdependence assumption between the dyad – see Table 2). All the models presented satisfactory goodness of fit, considering the model with the restricted factor loadings to be equal between

groups (CFI>0.91; RMSEA < 0.08, RMSEA < 0,001). Table 4 presents the parameters of the APIM for the CTS-Minor, considering the actor and partner effects for each of the FBQ's seven dimensions. The parameters represent the effect of regressions on the actor-partner interdependence models, analyzed with structural equations.

Table 4  
*APIM's parameters concerning the relationship between the FBQ dimensions and the CTS-Minor latent variable*

	CTS-Minor Parameters
<b>FBQ Physical neglect</b>	
Female actor effect	-0.133
Male actor effect	0.183**
Female partner effect	0.004
Male partner effect	0.007
<b>FBQ Maternal physical abuse</b>	
Female actor effect	0.188**
Male actor effect	0.181**
Female partner effect	0.079
Male partner effect	0.040
<b>FBQ Paternal substance abuse</b>	
Female actor effect	0.022
Male actor effect	0.013
Female partner effect	0.073
Male partner effect	-0.069
<b>FBQ Maternal substance abuse</b>	
Female actor effect	0.183*
Male actor effect	0.055
Female partner effect	-0.022
Male partner effect	-0.117
<b>FBQ Paternal psychological maladjustment</b>	
Female actor effect	0.285**
Male actor effect	0.104
Female partner effect	0.111
Male partner effect	0.138*
<b>FBQ Maternal psychological maladjustment</b>	
Female actor effect	0.295**
Male actor effect	0.223**
Female partner effect	0.125*
Male partner effect	0.080
<b>FBQ Parental Alliance</b>	
Female actor effect	0.305**
Male actor effect	0.065
Female partner effect	0.157*
Male partner effect	0.074

\* $p < 0.05$ ; \*\* $p < 0.01$

The results indicate that physical neglect experienced by a man in his family of origin was associated with violence he perpetrates. Maternal physical abuse influenced the violence perpetrated by men and women. Paternal substance abuse did not present significant associations; however, maternal substance abuse witnessed by a woman was related to the violence she perpetrates within the relationship. Paternal psychological maladjustment was significantly associated with violence perpetrated by women and the victimization of men. Maternal psychological maladjustment was associated with violence perpetrated and experienced by

women, and violence perpetrated by men. Finally, parental alliance was significantly associated, though with a small magnitude, with violence women perpetrate and experience; other variables may reflect on the violence phenomenon.

## Discussion

These results reinforce the power of events experienced in one's family of origin to predict behavioral models that repeat in adult relationships (Madalena et al., 2018). For male actors, some experiences from the family of origin influence the violence they perpetrate, such as neglect, maternal physical abuse, and maternal psychological maladjustment. Regarding physical neglect, it is known that its occurrence may trigger feelings of inability, worthlessness, and vulnerability (De Antoni & Batista, 2014).

Maternal physical abuse experienced during childhood was associated with violence perpetrated by men, which is in line with Moura et al. (2020), showing that men who reported physical abuse during childhood were more likely to perpetrate violence in a marital relationship. From the same perspective, Vieira, Perdoná, and Santos (2011) showed that women whose spouses were abused during childhood were three times more likely to be victimized.

Another experience from the family of origin that had an effect on male actors was maternal psychological maladjustment, which is when the mother presents psychological disorders. Thus, the parents' mental problems affect children and families (Bouvette-Turcot et al., 2017); the assumption is that parents/adults are supposed to meet the children's basic needs (i.e., physical, behavioral, and emotional needs) to ensure they develop healthy (Schavarem & Toni, 2019); otherwise, children may grow into adults with dysfunctional behavior and emotions. These results indicate that violent behavior may perpetuate in marital relationships.

When assessing the men's experiences in their families of origin, the male partner effect influenced the violence perpetrated by their spouses; that is, the male partner effect was associated with the paternal psychological maladjustment dimension. This finding is in line with Hou, Yu, Fang and Epstein (2016) that violence perpetrated by a man's parents makes this man more likely to be victimized by his spouse. However, these findings differ in terms of the parent's and child's genders. In this study, the men who experienced paternal psychological maladjustment were more likely to be victimized by their spouses. In the study above, when the aggressor was a man, they also perpetrated violence, as if they identified themselves with the aggressor.

Regarding the female actor effect, the women's experiences from their families of origin that influence the violence they perpetrate included: maternal physical abuse, maternal substance abuse, paternal and maternal psychological maladjustment, and parental alliance. These findings corroborate the notion that violence perpetrated by the mothers is probably the one with the most potent effect

(Hou et al., 2016) and that there is an association between the parent's genders with the aggressor's gender. Maternal physical abuse and maternal psychological maladjustment were associated with female aggressors, corroborating the findings reported by a previous study (Kerley, Xu, Sirisunyaluck, & Alley, 2010).

Scientific studies indicate that the mother (Pinto Junior, Cassepp-Borges, & Santos, 2015) is the primary kinship figure responsible for physical violence perpetrated against children. The hypothesis possibly explaining it is that mothers are the parental figure most frequently present (Nunes & Sales, 2016) and more frequently involved with domestic activities. There is a potential association between having experienced or experience intimate partner violence and a woman's violent parental conditions, increasing the likelihood they will also show violent upbringing practices (J.M.M. Silva et al., 2017). This finding is in line with the parental alliance variable, which influences the violence perpetrated by women. Parental alliance refers to the relationship between parents regarding how to raise their children and even the existence of a violent relationship between the couple. Carneiro et al. (2017) consider that the violence experienced by women compromises their physical and mental health and that of their children. Children who witness violence are more likely to experience violence in their future relationships.

Maternal substance use was associated with female actors. There may be a pattern in which female aggressors repeat substance abuse, which needs to be further investigated. One study (Cezario, Carvalho, & Lourenço, 2016) reveals that most of the men victimized by their spouses reported the presence of alcohol and drugs. When the female partner effect was assessed, the women's experiences from her family of origin that influenced the violence perpetrated by their spouses included maternal psychological maladjustment and parental alliance. Having a mother with mental problems and witnessing violence or disagreement in one's parents' marital relationship seems to compromise the daughters' future relationships. That is, they will likely seek partners that make them relive those experiences, with a potential association with reference figures (Tondowski et al., 2014).

These results show that men and women perpetrated violence and/or were victimized under the influence of different family experiences, ratifying the notion that these behaviors, even when re-signified, may repeat for generations, corroborating the transgenerational perspective of violence. Violence is a complex phenomenon; however, the results reveal that men and women are victimized or perpetrate violence in their marital relationships and the events experienced in their families of origin influence both the violence they experience and perpetrate.

Future studies can address different marital configurations, including same-sex couples so that the gender variable can be further explored in situations of intimate partner violence. One of this study's limitations refers to collecting data using a convenient sample

recruited from the general population; that is, this sample presented a low frequency of sexual abuse, which may explain why this variable did not present interdependence. Additionally, this study's cross-sectional design does not allow establishing causal relationships between the variables. Longitudinal studies including clinical populations are suggested.
